## PART 1

---

## Getting Started and General Information

---

### CHAPTER 1

## Introduction to the Cisco ASA 5500 Series Adaptive Security Appliance 1-1

ASA 5500 Model Support 1-1

Module Support 1-1

VPN Specifications 1-2

New Features 1-2

New Features in Version 8.3(2) 1-3

New Features in Version 8.3(1) 1-5

Firewall Functional Overview 1-10

Security Policy Overview 1-11

Permitting or Denying Traffic with Access Lists 1-11

Applying NAT 1-11

Protecting from IP Fragments 1-12

Using AAA for Through Traffic 1-12

Applying HTTP, HTTPS, or FTP Filtering 1-12

Applying Application Inspection 1-12

Sending Traffic to the Advanced Inspection and Prevention Security Services Module 1-12

Sending Traffic to the Content Security and Control Security Services Module 1-12

Applying QoS Policies 1-13

Applying Connection Limits and TCP Normalization 1-13

Enabling Threat Detection 1-13

Enabling the Botnet Traffic Filter 1-13

Configuring Cisco Unified Communications 1-13

Firewall Mode Overview 1-14

Stateful Inspection Overview 1-14

VPN Functional Overview 1-15

Security Context Overview 1-15

**CHAPTER 2**

**Getting Started 2-1**

- Factory Default Configurations 2-1
  - Restoring the Factory Default Configuration 2-2
  - ASA 5505 Default Configuration 2-2
  - ASA 5510 and Higher Default Configuration 2-4
- Accessing the Command-Line Interface 2-4
- Working with the Configuration 2-5
  - Saving Configuration Changes 2-6
    - Saving Configuration Changes in Single Context Mode 2-6
    - Saving Configuration Changes in Multiple Context Mode 2-6
  - Copying the Startup Configuration to the Running Configuration 2-8
  - Viewing the Configuration 2-8
  - Clearing and Removing Configuration Settings 2-9
  - Creating Text Configuration Files Offline 2-9
- Applying Configuration Changes to Connections 2-10

**CHAPTER 3**

**Managing Feature Licenses 3-1**

- Supported Feature Licenses Per Model 3-1
  - Licenses Per Model 3-2
  - License Notes 3-9
  - VPN License and Feature Compatibility 3-12
- Information About Feature Licenses 3-12
  - Preinstalled License 3-13
  - Permanent License 3-13
  - Time-Based Licenses 3-13
    - Time-Based License Activation Guidelines 3-13
    - How the Time-Based License Timer Works 3-13
    - How Permanent and Time-Based Licenses Combine 3-14
    - Stacking Time-Based Licenses 3-15
    - Time-Based License Expiration 3-15
- Shared SSL VPN Licenses 3-15
  - Information About the Shared Licensing Server and Participants 3-16
  - Communication Issues Between Participant and Server 3-17
  - Information About the Shared Licensing Backup Server 3-17
  - Failover and Shared Licenses 3-18
  - Maximum Number of Participants 3-19
  - Failover Licenses (8.3(1) and Later) 3-20

Failover License Requirements	3-20
How Failover Licenses Combine	3-20
Loss of Communication Between Failover Units	3-21
Upgrading Failover Pairs	3-21
Licenses FAQ	3-21
Guidelines and Limitations	3-22
Viewing Your Current License	3-24
Obtaining an Activation Key	3-29
Activating or Deactivating Keys	3-30
Configuring a Shared License	3-31
Configuring the Shared Licensing Server	3-32
Configuring the Shared Licensing Backup Server (Optional)	3-33
Configuring the Shared Licensing Participant	3-34
Monitoring the Shared License	3-35
Feature History for Licensing	3-36

## CHAPTER 4

<b>Configuring the Transparent or Routed Firewall</b>	<b>4-1</b>
Configuring the Firewall Mode	4-1
Information About the Firewall Mode	4-1
Information About Routed Firewall Mode	4-2
Information About Transparent Firewall Mode	4-2
Licensing Requirements for the Firewall Mode	4-4
Default Settings	4-4
Guidelines and Limitations	4-5
Setting the Firewall Mode	4-7
Feature History for Firewall Mode	4-8
Configuring ARP Inspection for the Transparent Firewall	4-8
Information About ARP Inspection	4-8
Licensing Requirements for ARP Inspection	4-9
Default Settings	4-9
Guidelines and Limitations	4-9
Configuring ARP Inspection	4-9
Task Flow for Configuring ARP Inspection	4-10
Adding a Static ARP Entry	4-10
Enabling ARP Inspection	4-11
Monitoring ARP Inspection	4-11
Feature History for ARP Inspection	4-11
Customizing the MAC Address Table for the Transparent Firewall	4-12
Information About the MAC Address Table	4-12

Licensing Requirements for the MAC Address Table	4-12
Default Settings	4-13
Guidelines and Limitations	4-13
Configuring the MAC Address Table	4-13
Adding a Static MAC Address	4-13
Setting the MAC Address Timeout	4-14
Disabling MAC Address Learning	4-14
Monitoring the MAC Address Table	4-15
Feature History for the MAC Address Table	4-15
Firewall Mode Examples	4-15
How Data Moves Through the Security Appliance in Routed Firewall Mode	4-16
An Inside User Visits a Web Server	4-16
An Outside User Visits a Web Server on the DMZ	4-17
An Inside User Visits a Web Server on the DMZ	4-19
An Outside User Attempts to Access an Inside Host	4-20
A DMZ User Attempts to Access an Inside Host	4-21
How Data Moves Through the Transparent Firewall	4-22
An Inside User Visits a Web Server	4-23
An Inside User Visits a Web Server Using NAT	4-24
An Outside User Visits a Web Server on the Inside Network	4-25
An Outside User Attempts to Access an Inside Host	4-26

---

**PART 2**

---

**Setting up the Adaptive Security Appliance**

---

**CHAPTER 5**

<b>Configuring Multiple Context Mode</b>	<b>5-1</b>
Information About Security Contexts	5-1
Common Uses for Security Contexts	5-2
Context Configuration Files	5-2
Context Configurations	5-2
System Configuration	5-2
Admin Context Configuration	5-2
How the Security Appliance Classifies Packets	5-3
Valid Classifier Criteria	5-3
Classification Examples	5-4
Cascading Security Contexts	5-6
Management Access to Security Contexts	5-7
System Administrator Access	5-7
Context Administrator Access	5-8
Information About Resource Management	5-8

Resource Limits	5-8
Default Class	5-9
Class Members	5-10
Information About MAC Addresses	5-11
Default MAC Address	5-11
Interaction with Manual MAC Addresses	5-11
Failover MAC Addresses	5-11
MAC Address Format	5-11
Licensing Requirements for Multiple Context Mode	5-12
Guidelines and Limitations	5-12
Default Settings	5-13
Configuring Multiple Contexts	5-13
Task Flow for Configuring Multiple Context Mode	5-13
Enabling or Disabling Multiple Context Mode	5-14
Enabling Multiple Context Mode	5-14
Restoring Single Context Mode	5-14
Configuring a Class for Resource Management	5-15
Configuring a Security Context	5-17
Automatically Assigning MAC Addresses to Context Interfaces	5-22
Changing Between Contexts and the System Execution Space	5-23
Managing Security Contexts	5-23
Removing a Security Context	5-24
Changing the Admin Context	5-24
Changing the Security Context URL	5-25
Reloading a Security Context	5-26
Reloading by Clearing the Configuration	5-26
Reloading by Removing and Re-adding the Context	5-27
Monitoring Security Contexts	5-27
Viewing Context Information	5-27
Viewing Resource Allocation	5-29
Viewing Resource Usage	5-32
Monitoring SYN Attacks in Contexts	5-33
Viewing Assigned MAC Addresses	5-35
Viewing MAC Addresses in the System Configuration	5-36
Viewing MAC Addresses Within a Context	5-37
Configuration Examples for Multiple Context Mode	5-38
Feature History for Multiple Context Mode	5-39

**CHAPTER 6****Configuring Interfaces 6-1**

Information About Interfaces 6-1

ASA 5505 Interfaces 6-2

Understanding ASA 5505 Ports and Interfaces 6-2

Maximum Active VLAN Interfaces for Your License 6-2

VLAN MAC Addresses 6-4

Power over Ethernet 6-4

Monitoring Traffic Using SPAN 6-5

Auto-MDI/MDIX Feature 6-5

Security Levels 6-5

Dual IP Stack 6-6

Management Interface (ASA 5510 and Higher) 6-6

Licensing Requirements for Interfaces 6-6

Guidelines and Limitations 6-7

Default Settings 6-8

Starting Interface Configuration (ASA 5510 and Higher) 6-8

Task Flow for Starting Interface Configuration 6-9

Enabling the Physical Interface and Configuring Ethernet Parameters 6-9

Configuring a Redundant Interface 6-11

Configuring a Redundant Interface 6-11

Changing the Active Interface 6-14

Configuring VLAN Subinterfaces and 802.1Q Trunking 6-14

Assigning Interfaces to Contexts and Automatically Assigning MAC Addresses (Multiple Context Mode) 6-15

Starting Interface Configuration (ASA 5505) 6-16

Task Flow for Starting Interface Configuration 6-16

Configuring VLAN Interfaces 6-16

Configuring and Enabling Switch Ports as Access Ports 6-17

Configuring and Enabling Switch Ports as Trunk Ports 6-20

Completing Interface Configuration (All Models) 6-22

Task Flow for Completing Interface Configuration 6-23

Entering Interface Configuration Mode 6-23

Configuring General Interface Parameters 6-24

Configuring the MAC Address 6-26

Configuring IPv6 Addressing 6-27

Allowing Same Security Level Communication 6-30

Enabling Jumbo Frame Support (ASA 5580) 6-31

Monitoring Interfaces 6-32

Configuration Examples for Interfaces	6-32
Physical Interface Parameters Example	6-32
Subinterface Parameters Example	6-32
Multiple Context Mode Examples	6-32
ASA 5505 Example	6-33
Feature History for Interfaces	6-34

## CHAPTER 7

### Configuring Basic Settings 7-1

Configuring the Hostname, Domain Name, and Passwords	7-1
Changing the Login Password	7-1
Changing the Enable Password	7-2
Setting the Hostname	7-2
Setting the Domain Name	7-3
Setting the Date and Time	7-3
Setting the Time Zone and Daylight Saving Time Date Range	7-4
Setting the Date and Time Using an NTP Server	7-5
Setting the Date and Time Manually	7-6
Configuring the Master Passphrase	7-6
Information About the Master Passphrase	7-6
Licensing Requirements for the Master Passphrase	7-7
Guidelines and Limitations	7-7
Adding or Changing the Master Passphrase	7-7
Disabling the Master Passphrase	7-9
Recovering the Master Passphrase	7-10
Feature History for the Master Passphrase	7-11
Configuring the DNS Server	7-11
Setting the Management IP Address for a Transparent Firewall	7-12
Information About the Management IP Address	7-12
Licensing Requirements for the Management IP Address for a Transparent Firewall	7-13
Guidelines and Limitations	7-13
Configuring the IPv4 Address	7-14
Configuring the IPv6 Address	7-14
Configuration Examples for the Management IP Address for a Transparent Firewall	7-14
Feature History for the Management IP Address for a Transparent Firewall	7-15

## CHAPTER 8

### Configuring DHCP 8-1

Information About DHCP	8-1
Licensing Requirements for DHCP	8-1

Guidelines and Limitations	8-2
Configuring a DHCP Server	8-2
Enabling the DHCP Server	8-3
Configuring DHCP Options	8-4
Options that Return an IP Address	8-4
Options that Return a Text String	8-4
Options that Return a Hexadecimal Value	8-5
Using Cisco IP Phones with a DHCP Server	8-6
Configuring DHCP Relay Services	8-7
DHCP Monitoring Commands	8-8
Feature History for DHCP	8-8

## CHAPTER 9

<b>Configuring Dynamic DNS</b>	<b>9-1</b>
Information about DDNS	9-1
Licensing Requirements for DDNS	9-2
Guidelines and Limitations	9-2
Configuring DDNS	9-2
Configuration Examples for DDNS	9-3
Example 1: Client Updates Both A and PTR RRs for Static IP Addresses	9-3
Example 2: Client Updates Both A and PTR RRs; DHCP Server Honors Client Update Request; FQDN Provided Through Configuration	9-3
Example 3: Client Includes FQDN Option Instructing Server Not to Update Either RR; Server Overrides Client and Updates Both RRs.	9-4
Example 4: Client Asks Server To Perform Both Updates; Server Configured to Update PTR RR Only; Honors Client Request and Updates Both A and PTR RR	9-5
Example 5: Client Updates A RR; Server Updates PTR RR	9-5
DDNS Monitoring Commands	9-6
Feature History for DDNS	9-6

## CHAPTER 10

<b>Configuring Web Cache Services Using WCCP</b>	<b>10-1</b>
Information About WCCP	10-1
Guidelines and Limitations	10-1
Licensing Requirements for WCCP	10-2
Enabling WCCP Redirection	10-3
WCCP Monitoring Commands	10-4
Feature History for WCCP	10-4

**CHAPTER 11****Configuring Objects 11-1**

- Configuring Objects and Groups 11-1
  - Information About Objects and Groups 11-1
    - Information About Objects 11-2
    - Information About Object Groups 11-2
  - Licensing Requirements for Objects and Groups 11-2
  - Guidelines and Limitations for Objects and Groups 11-3
  - Configuring Objects 11-3
    - Configuring a Network Object 11-3
    - Configuring a Service Object 11-4
  - Configuring Object Groups 11-6
    - Adding a Protocol Object Group 11-6
    - Adding a Network Object Group 11-7
    - Adding a Service Object Group 11-8
    - Adding an ICMP Type Object Group 11-9
    - Nesting Object Groups 11-10
    - Removing Object Groups 11-11
  - Monitoring Objects and Groups 11-11
  - Feature History for Objects and Groups 11-12
- Configuring Regular Expressions 11-12
  - Creating a Regular Expression 11-12
  - Creating a Regular Expression Class Map 11-15
- Scheduling Extended Access List Activation 11-16
  - Information About Scheduling Access List Activation 11-16
  - Licensing Requirements for Scheduling Access List Activation 11-16
  - Guidelines and Limitations for Scheduling Access List Activation 11-16
  - Configuring and Applying Time Ranges 11-17
  - Configuration Examples for Scheduling Access List Activation 11-18
  - Feature History for Scheduling Access List Activation 11-18

**PART 3****Configuring Access Lists****CHAPTER 12****Information About Access Lists 12-1**

- Access List Types 12-1
- Access Control Entry Order 12-2
- Access Control Implicit Deny 12-3
- IP Addresses Used for Access Lists When You Use NAT 12-3
- Where to Go Next 12-3

## CHAPTER 13

### **Adding an Extended Access List 13-1**

- Information About Extended Access Lists 13-1
- Licensing Requirements for Extended Access Lists 13-1
- Guidelines and Limitations 13-2
- Default Settings 13-2
- Configuring Extended Access Lists 13-3
  - Adding an Extended Access List 13-3
  - Adding Remarks to Access Lists 13-5
- Monitoring Extended Access Lists 13-5
- Configuration Examples for Extended Access Lists 13-5
  - Configuration Examples for Extended Access Lists (No Objects) 13-6
  - Configuration Examples for Extended Access Lists (Using Objects) 13-6
- Where to Go Next 13-7
- Feature History for Extended Access Lists 13-7

## CHAPTER 14

### **Adding an EtherType Access List 14-1**

- Information About EtherType Access Lists 14-1
- Licensing Requirements for EtherType Access Lists 14-1
- Guidelines and Limitations 14-2
- Default Settings 14-2
- Configuring EtherType Access Lists 14-2
  - Task Flow for Configuring EtherType Access Lists 14-2
  - Adding EtherType Access Lists 14-3
  - Adding Remarks to Access Lists 14-4
- What to Do Next 14-4
- Monitoring EtherType Access Lists 14-4
- Configuration Examples for EtherType Access Lists 14-5
- Feature History for EtherType Access Lists 14-5

## CHAPTER 15

### **Adding a Standard Access List 15-1**

- Information About Standard Access Lists 15-1
- Licensing Requirements for Standard Access Lists 15-1
- Guidelines and Limitations 15-1
- Default Settings 15-2
- Adding Standard Access Lists 15-3
  - Task Flow for Configuring Extended Access Lists 15-3
  - Adding a Standard Access List 15-3

Adding Remarks to Access Lists	15-4
What to Do Next	15-4
Monitoring Access Lists	15-4
Configuration Examples for Standard Access Lists	15-5
Feature History for Standard Access Lists	15-5

---

**CHAPTER 16**

<b>Adding a Webtype Access List</b>	<b>16-1</b>
Licensing Requirements for Webtype Access Lists	16-1
Guidelines and Limitations	16-1
Default Settings	16-2
Using Webtype Access Lists	16-2
Task Flow for Configuring Webtype Access Lists	16-2
Adding Webtype Access Lists with a URL String	16-3
Adding Webtype Access Lists with an IP Address	16-4
Adding Remarks to Access Lists	16-5
What to Do Next	16-5
Monitoring Webtype Access Lists	16-5
Configuration Examples for Webtype Access Lists	16-6
Feature History for Webtype Access Lists	16-7

---

**CHAPTER 17**

<b>Adding an IPv6 Access List</b>	<b>17-1</b>
Information About IPv6 Access Lists	17-1
Licensing Requirements for IPv6 Access Lists	17-1
Prerequisites for Adding IPv6 Access Lists	17-2
Guidelines and Limitations	17-2
Default Settings	17-3
Configuring IPv6 Access Lists	17-4
Task Flow for Configuring IPv6 Access Lists	17-4
Adding IPv6 Access Lists	17-5
Adding Remarks to Access Lists	17-6
Monitoring IPv6 Access Lists	17-7
Configuration Examples for IPv6 Access Lists	17-7
Where to Go Next	17-7
Feature History for IPv6 Access Lists	17-7

---

**CHAPTER 18**

<b>Configuring Logging for Access Lists</b>	<b>18-1</b>
Configuring Logging for Access Lists	18-1

Information About Logging Access List Activity	18-1
Licensing Requirements for Access List Logging	18-2
Guidelines and Limitations	18-2
Default Settings	18-3
Configuring Access List Logging	18-3
Monitoring Access Lists	18-4
Configuration Examples for Access List Logging	18-4
Feature History for Access List Logging	18-5
Managing Deny Flows	18-5
Information About Managing Deny Flows	18-6
Licensing Requirements for Managing Deny Flows	18-6
Guidelines and Limitations	18-6
Default Settings	18-7
Managing Deny Flows	18-7
Monitoring Deny Flows	18-8
Feature History for Managing Deny Flows	18-8

## PART 4

## Configuring IP Routing

### CHAPTER 19

<b>Information About Routing</b>	<b>19-1</b>
Information About Routing	19-1
Switching	19-1
Path Determination	19-2
Supported Route Types	19-2
Static Versus Dynamic	19-2
Single-Path Versus Multipath	19-3
Flat Versus Hierarchical	19-3
Link-State Versus Distance Vector	19-3
How Routing Behaves Within the Adaptive Security Appliance	19-4
Egress Interface Selection Process	19-4
Next Hop Selection Process	19-4
Supported Internet Protocols for Routing	19-5
Information About the Routing Table	19-5
Displaying the Routing Table	19-5
How the Routing Table Is Populated	19-6
Backup Routes	19-8
How Forwarding Decisions are Made	19-8
Dynamic Routing and Failover	19-8
Information About IPv6 Support	19-9

Features that Support IPv6	19-9
IPv6-Enabled Commands	19-10
IPv6 Command Guidelines in Transparent Firewall Mode	19-10
Entering IPv6 Addresses in Commands	19-11
Disabling Proxy ARPs	19-11

## CHAPTER 20

<b>Configuring Static and Default Routes</b>	20-1
Information About Static and Default Routes	20-1
Licensing Requirements for Static and Default Routes	20-2
Guidelines and Limitations	20-2
Configuring Static and Default Routes	20-2
Configuring a Static Route	20-3
Add/Edit a Static Route	20-3
Configuring a Default Static Route	20-4
Limitations on Configuring a Default Static Route	20-4
Configuring IPv6 Default and Static Routes	20-5
Monitoring a Static or Default Route	20-6
Configuration Examples for Static or Default Routes	20-8
Feature History for Static and Default Routes	20-9

## CHAPTER 21

<b>Defining Route Maps</b>	21-1
Route Maps Overview	21-1
Permit and Deny Clauses	21-2
Match and Set Clause Values	21-2
Licensing Requirements for Route Maps	21-3
Guidelines and Limitations	21-3
Defining a Route Map	21-4
Customizing a Route Map	21-4
Defining a Route to Match a Specific Destination Address	21-4
Configuring the Metric Values for a Route Action	21-5
Configuration Example for Route Maps	21-6
Feature History for Route Maps	21-6

## CHAPTER 22

<b>Configuring OSPF</b>	22-1
Information About OSPF	22-1
Licensing Requirements for OSPF	22-3
Guidelines and Limitations	22-3

Configuring OSPF	22-3
Customizing OSPF	22-4
Redistributing Routes Into OSPF	22-4
Configuring Route Summarization When Redistributing Routes into OSPF	22-6
Configuring Route Summarization Between OSPF Areas	22-7
Configuring OSPF Interface Parameters	22-8
Configuring OSPF Area Parameters	22-10
Configuring OSPF NSSA	22-11
Defining Static OSPF Neighbors	22-12
Configuring Route Calculation Timers	22-13
Logging Neighbors Going Up or Down	22-14
Restarting the OSPF Process	22-14
Configuration Example for OSPF	22-14
Monitoring OSPF	22-16
Feature History for OSPF	22-17

---

**CHAPTER 23**
**Configuring RIP 23-1**

Overview	23-1
Routing Update Process	23-2
RIP Routing Metric	23-2
RIP Stability Features	23-2
RIP Timers	23-2
Licensing Requirements for RIP	23-2
Guidelines and Limitations	23-3
Configuring RIP	23-3
Enabling RIP	23-4
Customizing RIP	23-4
Configure the RIP Version	23-5
Configuring Interfaces for RIP	23-6
Configuring the RIP Send and Receive Version on an Interface	23-6
Configuring Route Summarization	23-7
Filtering Networks in RIP	23-8
Redistributing Routes into the RIP Routing Process	23-8
Enabling RIP Authentication	23-9
Restarting the RIP Process	23-10
Monitoring RIP	23-11
Configuration Example for RIP	23-11
Feature History for RIP	23-12

**CHAPTER 24****Configuring EIGRP 24-1**

- Overview 24-1
- Licensing Requirements for EIGRP 24-2
- Guidelines and Limitations 24-2
- Configuring EIGRP 24-3
  - Enabling EIGRP 24-3
  - Enabling EIGRP Stub Routing 24-4
- Customizing EIGRP 24-5
  - Defining a Network for an EIGRP Routing Process 24-5
  - Configuring Interfaces for EIGRP 24-6
    - Configuring Passive Interfaces 24-8
  - Configuring the Summary Aggregate Addresses on Interfaces 24-8
  - Changing the Interface Delay Value 24-9
  - Enabling EIGRP Authentication on an Interface 24-9
  - Defining an EIGRP Neighbor 24-11
  - Redistributing Routes Into EIGRP 24-11
  - Filtering Networks in EIGRP 24-13
  - Customizing the EIGRP Hello Interval and Hold Time 24-14
  - Disabling Automatic Route Summarization 24-15
  - Configuring Default Information in EIGRP 24-15
  - Disabling EIGRP Split Horizon 24-16
  - Restarting the EIGRP Process 24-17
- Monitoring EIGRP 24-17
- Configuration Example for EIGRP 24-18
- Feature History for EIGRP 24-19

**CHAPTER 25****Configuring Multicast Routing 25-1**

- Information About Multicast Routing 25-1
  - Stub Multicast Routing 25-2
  - PIM Multicast Routing 25-2
  - Multicast Group Concept 25-2
    - Multicast Addresses 25-2
- Licensing Requirements for Multicast Routing 25-2
- Guidelines and Limitations 25-3
- Enabling Multicast Routing 25-3
- Customizing Multicast Routing 25-4
  - Configuring Stub Multicast Routing 25-4
  - Configuring a Static Multicast Route 25-4

Configuring IGMP Features	25-5
Disabling IGMP on an Interface	25-6
Configuring IGMP Group Membership	25-6
Configuring a Statically Joined IGMP Group	25-6
Controlling Access to Multicast Groups	25-7
Limiting the Number of IGMP States on an Interface	25-7
Modifying the Query Messages to Multicast Groups	25-8
Changing the IGMP Version	25-9
Configuring PIM Features	25-9
Enabling and Disabling PIM on an Interface	25-10
Configuring a Static Rendezvous Point Address	25-10
Configuring the Designated Router Priority	25-11
Configuring and Filtering PIM Register Messages	25-11
Configuring PIM Message Intervals	25-12
Filtering PIM Neighbors	25-12
Configuring a Bidirectional Neighbor Filter	25-13
Configuring a Multicast Boundary	25-14
Configuration Example for Multicast Routing	25-14
Additional References	25-15
Related Documents	25-15
RFCs	25-15
Feature History for Multicast Routing	25-15
<b>CHAPTER 26</b>	
<b>Configuring IPv6 Neighbor Discovery</b>	<b>26-1</b>
Configuring Neighbor Solicitation Messages	26-1
Configuring the Neighbor Solicitation Message Interval	26-1
Information About Neighbor Solicitation Messages	26-2
Licensing Requirements for Neighbor Solicitation Messages	26-2
Guidelines and Limitations for the Neighbor Solicitation Message Interval	26-3
Default Settings for the Neighbor Solicitation Message Interval	26-3
Configuring the Neighbor Solicitation Message Interval	26-3
Monitoring Neighbor Solicitation Message Intervals	26-4
Feature History for the Neighbor Solicitation Message Interval	26-4
Configuring the Neighbor Reachable Time	26-4
Information About Neighbor Reachable Time	26-5
Licensing Requirements for Neighbor Reachable Time	26-5
Guidelines and Limitations for Neighbor Reachable Time	26-5
Default Settings for the Neighbor Reachable Time	26-5
Configuring Neighbor Reachable Time	26-6

Monitoring Neighbor Reachable Time	26-6
Feature History for Neighbor Reachable Time	26-7
Configuring Router Advertisement Messages	26-7
Information About Router Advertisement Messages	26-7
Configuring the Router Advertisement Transmission Interval	26-8
Licensing Requirements for Router Advertisement Transmission Interval	26-9
Guidelines and Limitations for the Router Advertisement Transmission Interval	26-9
Default Settings for Router Advertisement Transmission Interval	26-9
Configuring Router Advertisement Transmission Interval	26-9
Monitoring the Router Advertisement Transmission Interval	26-10
Feature History for the Router Advertisement Transmission Interval	26-10
Configuring the Router Lifetime Value	26-11
Licensing Requirements for the Router Lifetime Value	26-11
Guidelines and Limitations for the Router Lifetime Value	26-11
Default Settings for the Router Lifetime Value	26-11
Configuring the Router Lifetime Value	26-11
Monitoring the Router Lifetime Value	26-12
Where to Go Next	26-13
Feature History for the Router Lifetime Value	26-13
Configuring the IPv6 Prefix	26-13
Licensing Requirements for IPv6 Prefixes	26-13
Guidelines and Limitations for IPv6 Prefixes	26-13
Default Settings for IPv6 Prefixes	26-14
Configuring IPv6 Prefixes	26-15
Additional References	26-16
Feature History for IPv6 Prefixes	26-17
Suppressing Router Advertisement Messages	26-17
Licensing Requirements for Suppressing Router Advertisement Messages	26-17
Guidelines and Limitations for Suppressing Router Advertisement Messages	26-18
Default Settings for Suppressing Router Advertisement Messages	26-18
Suppressing Router Advertisement Messages	26-18
Feature History for Suppressing Router Advertisement Messages	26-19
Configuring a Static IPv6 Neighbor	26-19
Information About a Static IPv6 Neighbor	26-20
Licensing Requirements for Static IPv6 Neighbor	26-20
Guidelines and Limitations	26-20
Default Settings	26-21
Configuring a Static IPv6 Neighbor	26-21
Monitoring Neighbor Solicitation Messages	26-22
Feature History for Configuring a Static IPv6 Neighbor	26-22

**PART 5**

**Configuring Network Address Translation**

**CHAPTER 27**

**Information About NAT 27-1**

- Why Use NAT? 27-1
- NAT Terminology 27-2
- NAT Types 27-2
  - Static NAT 27-3
    - Information About Static NAT 27-3
    - Information About Static NAT with Port Translation 27-3
    - Information About One-to-Many Static NAT 27-6
    - Information About Other Mapping Scenarios (Not Recommended) 27-7
  - Dynamic NAT 27-8
    - Information About Dynamic NAT 27-9
    - Dynamic NAT Disadvantages and Advantages 27-10
  - Dynamic PAT 27-10
    - Information About Dynamic PAT 27-10
    - Dynamic PAT Disadvantages and Advantages 27-11
  - Identity NAT 27-11
- NAT in Routed and Transparent Mode 27-12
  - NAT in Routed Mode 27-13
  - NAT in Transparent Mode 27-13
- How NAT is Implemented 27-15
  - Main Differences Between Network Object NAT and Twice NAT 27-15
  - Information About Network Object NAT 27-16
  - Information About Twice NAT 27-16
- NAT Rule Order 27-19
- NAT Interfaces 27-20
- Mapped Address Guidelines 27-20
- DNS and NAT 27-21
- Where to Go Next 27-23

**CHAPTER 28**

**Configuring Network Object NAT 28-1**

- Information About Network Object NAT 28-1
- Licensing Requirements for Network Object NAT 28-2
- Prerequisites for Network Object NAT 28-2
- Guidelines and Limitations 28-2
- Configuring Network Object NAT 28-3
  - Configuring Dynamic NAT 28-4

Configuring Dynamic PAT (Hide)	28-6
Configuring Static NAT or Static NAT with Port Translation	28-8
Configuring Identity NAT	28-10
Monitoring Network Object NAT	28-11
Configuration Examples for Network Object NAT	28-12
Providing Access to an Inside Web Server (Static NAT)	28-13
NAT for Inside Hosts (Dynamic NAT) and NAT for an Outside Web Server (Static NAT)	28-13
Inside Load Balancer with Multiple Mapped Addresses (Static NAT, One-to-Many)	28-15
Single Address for FTP, HTTP, and SMTP (Static NAT with Port Translation)	28-16
DNS Server on Mapped Interface, Web Server on Real Interface (Static NAT with DNS Modification)	28-17
DNS Server and Web Server on Mapped Interface, Web Server is Translated (Static NAT with DNS Modification)	28-19
Feature History for Network Object NAT	28-20

---

**CHAPTER 29**
**Configuring Twice NAT** 29-1

Information About Twice NAT	29-1
Licensing Requirements for Twice NAT	29-2
Prerequisites for Twice NAT	29-2
Guidelines and Limitations	29-2
Configuring Twice NAT	29-3
Configuring Dynamic NAT	29-3
Configuring Dynamic PAT (Hide)	29-8
Configuring Static NAT or Static NAT with Port Translation	29-12
Configuring Identity NAT	29-17
Monitoring Twice NAT	29-20
Configuration Examples for Twice NAT	29-20
Different Translation Depending on the Destination (Dynamic PAT)	29-20
Different Translation Depending on the Destination Address and Port (Dynamic PAT)	29-22
Feature History for Twice NAT	29-23

---

**PART 6**

---

**Configuring Service Policies Using the Modular Policy Framework**

---

**CHAPTER 30**
**Configuring a Service Policy Using the Modular Policy Framework** 30-1

Information About Service Policies	30-1
Supported Features for Through Traffic	30-2
Supported Features for Management Traffic	30-2
Feature Directionality	30-2

Feature Matching Within a Service Policy	30-3
Order in Which Multiple Feature Actions are Applied	30-4
Incompatibility of Certain Feature Actions	30-5
Feature Matching for Multiple Service Policies	30-6
Licensing Requirements for Service Policies	30-6
Guidelines and Limitations	30-6
Default Settings	30-8
Default Configuration	30-8
Default Class Maps	30-9
Task Flows for Configuring Service Policies	30-9
Task Flow for Using the Modular Policy Framework	30-9
Task Flow for Configuring Hierarchical Policy Maps for QoS Traffic Shaping	30-11
Identifying Traffic (Layer 3/4 Class Maps)	30-12
Creating a Layer 3/4 Class Map for Through Traffic	30-12
Creating a Layer 3/4 Class Map for Management Traffic	30-15
Defining Actions (Layer 3/4 Policy Map)	30-15
Applying Actions to an Interface (Service Policy)	30-17
Monitoring Modular Policy Framework	30-18
Configuration Examples for Modular Policy Framework	30-18
Applying Inspection and QoS Policing to HTTP Traffic	30-19
Applying Inspection to HTTP Traffic Globally	30-19
Applying Inspection and Connection Limits to HTTP Traffic to Specific Servers	30-20
Applying Inspection to HTTP Traffic with NAT	30-21
Feature History for Service Policies	30-21

## CHAPTER 31

## Configuring Special Actions for Application Inspections (Inspection Policy Map) 31-1

Information About Inspection Policy Maps	31-1
Default Inspection Policy Maps	31-2
Defining Actions in an Inspection Policy Map	31-2
Identifying Traffic in an Inspection Class Map	31-5
Where to Go Next	31-6

## PART 7

## Configuring Access Control

## CHAPTER 32

## Configuring Access Rules 32-1

Information About Access Rules	32-1
General Information About Rules	32-2

Implicit Permits	32-2
Using Access Rules and EtherType Rules on the Same Interface	32-2
Inbound and Outbound Rules	32-2
Using Global Access Rules	32-4
Information About Extended Access Rules	32-4
Access Rules for Returning Traffic	32-4
Allowing Broadcast and Multicast Traffic through the Transparent Firewall Using Access Rules	32-4
Management Access Rules	32-5
Information About EtherType Rules	32-5
Supported EtherTypes	32-5
Access Rules for Returning Traffic	32-5
Allowing MPLS	32-6
Licensing Requirements for Access Rules	32-6
Prerequisites	32-6
Guidelines and Limitations	32-6
Default Settings	32-7
Configuring Access Rules	32-7
Monitoring Access Rules	32-8
Configuration Examples for Permitting or Denying Network Access	32-8
Feature History for Access Rules	32-9

## CHAPTER 33

## Configuring AAA Servers and the Local Database 33-1

AAA Overview	33-1
About Authentication	33-2
About Authorization	33-2
About Accounting	33-3
AAA Server and Local Database Support	33-3
Summary of Support	33-3
RADIUS Server Support	33-4
Authentication Methods	33-4
Attribute Support	33-5
RADIUS Authorization Functions	33-5
TACACS+ Server Support	33-5
RSA/SDI Server Support	33-5
RSA/SDI Version Support	33-6
Two-step Authentication Process	33-6
RSA/SDI Primary and Replica Servers	33-6
NT Server Support	33-6

Kerberos Server Support	33-6
LDAP Server Support	33-7
HTTP Forms Authentication for Clientless SSL VPN	33-7
Local Database Support	33-7
User Profiles	33-7
Fallback Support	33-7
Configuring the Local Database	33-8
Identifying AAA Server Groups and Servers	33-11
How Fallback Works with Multiple Servers in a Group	33-11
Configuring an LDAP Server	33-15
Authentication with LDAP	33-15
Securing LDAP Authentication with SASL	33-15
Setting the LDAP Server Type	33-16
Authorization with LDAP for VPN	33-17
LDAP Attribute Mapping for Authorization	33-18
Using Certificates and User Login Credentials	33-20
Using User Login Credentials	33-20
Using Certificates	33-21
Differentiating User Roles Using AAA	33-21
Using Local Authentication	33-22
Using RADIUS Authentication	33-22
Using LDAP Authentication	33-23
Using TACACS+ Authentication	33-23
AAA Servers Monitoring Commands	33-23
Additional References	33-24
Related Documents	33-25
RFCs	33-25
Feature History for AAA Servers	33-25

## CHAPTER 34

### Configuring Management Access 34-1

Configuring Device Access for ASDM, Telnet, or SSH	34-1
Configuring Telnet Access	34-2
Configuring SSH Access	34-3
Using an SSH Client	34-4
Configuring HTTPS Access for ASDM	34-5
Enabling HTTPS Access	34-5
Accessing ASDM from Your PC	34-6
Configuring CLI Parameters	34-6

Configuring a Login Banner	34-6
Customizing a CLI Prompt	34-7
Changing the Console Timeout Period	34-8
Configuring ICMP Access	34-8
Configuring Management Access Over a VPN Tunnel	34-10
Configuring AAA for System Administrators	34-10
Configuring Authentication for CLI and ASDM Access	34-11
Configuring Authentication To Access Privileged EXEC Mode (the enable Command)	34-12
Configuring Authentication for the enable Command	34-12
Authenticating Users with the login Command	34-12
Limiting User CLI and ASDM Access with Management Authorization	34-13
Configuring Command Authorization	34-14
Command Authorization Overview	34-14
Configuring Local Command Authorization	34-16
Configuring TACACS+ Command Authorization	34-21
Configuring Management Access Accounting	34-25
Viewing the Current Logged-In User	34-26
Recovering from a Lockout	34-27

## CHAPTER 35

### Configuring AAA Rules for Network Access 35-1

AAA Performance	35-1
Configuring Authentication for Network Access	35-1
Authentication Overview	35-2
One-Time Authentication	35-2
Applications Required to Receive an Authentication Challenge	35-2
Adaptive Security Appliance Authentication Prompts	35-2
Static PAT and HTTP	35-3
Enabling Network Access Authentication	35-4
Enabling Secure Authentication of Web Clients	35-5
Authenticating Directly with the Adaptive Security Appliance	35-6
Enabling Direct Authentication Using HTTP and HTTPS	35-6
Enabling Direct Authentication Using Telnet	35-7
Configuring Authorization for Network Access	35-8
Configuring TACACS+ Authorization	35-8
Configuring RADIUS Authorization	35-10
Configuring a RADIUS Server to Send Downloadable Access Control Lists	35-10
Configuring a RADIUS Server to Download Per-User Access Control List Names	35-14
Configuring Accounting for Network Access	35-14
Using MAC Addresses to Exempt Traffic from Authentication and Authorization	35-16

## CHAPTER 36

### Configuring Filtering Services 36-1

- Information About Web Traffic Filtering 36-1
- Configuring ActiveX Filtering 36-2
  - Information About ActiveX Filtering 36-2
- Licensing Requirements for ActiveX Filtering 36-2
  - Guidelines and Limitations for ActiveX Filtering 36-3
  - Configuring ActiveX Filtering 36-3
  - Configuration Examples for ActiveX Filtering 36-3
  - Feature History for ActiveX Filtering 36-4
- Configuring Java Applet Filtering 36-4
  - Information About Java Applet Filtering 36-4
  - Licensing Requirements for Java Applet Filtering 36-4
  - Guidelines and Limitations for Java Applet Filtering 36-5
  - Configuring Java Applet Filtering 36-5
  - Configuration Examples for Java Applet Filtering 36-5
  - Feature History for Java Applet Filtering 36-6
- Filtering URLs and FTP Requests with an External Server 36-6
  - Information About URL Filtering 36-6
  - Licensing Requirements for URL Filtering 36-7
  - Guidelines and Limitations for URL Filtering 36-7
  - Identifying the Filtering Server 36-7
  - Configuring Additional URL Filtering Settings 36-9
    - Buffering the Content Server Response 36-9
    - Caching Server Addresses 36-10
    - Filtering HTTP URLs 36-10
    - Filtering HTTPS URLs 36-12
    - Filtering FTP Requests 36-13
- Monitoring Filtering Statistics 36-14
  - Feature History for URL Filtering 36-16

## CHAPTER 37

### Configuring Digital Certificates 37-1

- Information About Digital Certificates 37-1
  - Public Key Cryptography 37-2
  - Certificate Scalability 37-2
  - Key Pairs 37-2
  - Trustpoints 37-3
    - Certificate Enrollment 37-3
  - Revocation Checking 37-4
    - CRLs 37-4

Supported CA Servers	37-5
OCSP	37-5
The Local CA	37-6
Storage for Local CA Files	37-6
The Local CA Server	37-6
Licensing Requirements for Digital Certificates	37-7
Prerequisites for Certificates	37-7
Guidelines and Limitations	37-8
Configuring Digital Certificates	37-8
Configuring Key Pairs	37-9
Removing Key Pairs	37-9
Configuring Trustpoints	37-10
Configuring CRLs for a Trustpoint	37-12
Exporting a Trustpoint Configuration	37-14
Importing a Trustpoint Configuration	37-15
Configuring CA Certificate Map Rules	37-16
Obtaining Certificates Manually	37-16
Obtaining Certificates Automatically with SCEP	37-19
Enabling the Local CA Server	37-20
Configuring the Local CA Server	37-21
Customizing the Local CA Server	37-23
Debugging the Local CA Server	37-25
Disabling the Local CA Server	37-25
Deleting the Local CA Server	37-25
Configuring Local CA Certificate Characteristics	37-26
Configuring the Issuer Name	37-27
Configuring the CA Certificate Lifetime	37-27
Configuring the User Certificate Lifetime	37-29
Configuring the CRL Lifetime	37-29
Configuring the Server Keysize	37-30
Setting Up External Local CA File Storage	37-31
Downloading CRLs	37-33
Storing CRLs	37-34
Setting Up Enrollment Parameters	37-35
Adding and Enrolling Users	37-36
Renewing Users	37-38
Restoring Users	37-39
Removing Users	37-39
Revoking Certificates	37-40

Maintaining the Local CA Certificate Database	37-40
Rolling Over Local CA Certificates	37-40
Archiving the Local CA Server Certificate and Keypair	37-41
Monitoring Digital Certificates	37-41
Feature History for Certificate Management	37-43

## PART 8

### Configuring Application Inspection

#### CHAPTER 38

#### Getting Started With Application Layer Protocol Inspection 38-1

Information about Application Layer Protocol Inspection	38-1
How Inspection Engines Work	38-1
When to Use Application Protocol Inspection	38-2
Guidelines and Limitations	38-3
Default Settings	38-4
Configuring Application Layer Protocol Inspection	38-6

#### CHAPTER 39

#### Configuring Inspection of Basic Internet Protocols 39-1

DNS Inspection	39-1
How DNS Application Inspection Works	39-2
How DNS Rewrite Works	39-2
Configuring DNS Rewrite	39-3
Configuring DNS Rewrite with Two NAT Zones	39-4
Overview of DNS Rewrite with Three NAT Zones	39-4
Configuring DNS Rewrite with Three NAT Zones	39-6
Configuring a DNS Inspection Policy Map for Additional Inspection Control	39-7
Verifying and Monitoring DNS Inspection	39-10
FTP Inspection	39-11
FTP Inspection Overview	39-11
Using the <b>strict</b> Option	39-11
Configuring an FTP Inspection Policy Map for Additional Inspection Control	39-12
Verifying and Monitoring FTP Inspection	39-16
HTTP Inspection	39-18
HTTP Inspection Overview	39-18
Configuring an HTTP Inspection Policy Map for Additional Inspection Control	39-19
ICMP Inspection	39-23
ICMP Error Inspection	39-23
Instant Messaging Inspection	39-23
IM Inspection Overview	39-23

Configuring an Instant Messaging Inspection Policy Map for Additional Inspection Control	39-24
IP Options Inspection	39-26
IP Options Inspection Overview	39-27
Configuring an IP Options Inspection Policy Map for Additional Inspection Control	39-28
IPSec Pass Through Inspection	39-28
IPSec Pass Through Inspection Overview	39-29
Example for Defining an IPSec Pass Through Parameter Map	39-29
NetBIOS Inspection	39-29
NetBIOS Inspection Overview	39-30
Configuring a NetBIOS Inspection Policy Map for Additional Inspection Control	39-30
PPTP Inspection	39-31
SMTP and Extended SMTP Inspection	39-32
SMTP and ESMTP Inspection Overview	39-32
Configuring an ESMTP Inspection Policy Map for Additional Inspection Control	39-33
TFTP Inspection	39-35

## CHAPTER 40

## Configuring Inspection for Voice and Video Protocols 40-1

CTIQBE Inspection	40-1
CTIQBE Inspection Overview	40-1
Limitations and Restrictions	40-2
Verifying and Monitoring CTIQBE Inspection	40-2
H.323 Inspection	40-3
H.323 Inspection Overview	40-4
How H.323 Works	40-4
H.239 Support in H.245 Messages	40-5
Limitations and Restrictions	40-6
Configuring an H.323 Inspection Policy Map for Additional Inspection Control	40-6
Configuring H.323 and H.225 Timeout Values	40-9
Verifying and Monitoring H.323 Inspection	40-9
Monitoring H.225 Sessions	40-9
Monitoring H.245 Sessions	40-10
Monitoring H.323 RAS Sessions	40-10
MGCP Inspection	40-11
MGCP Inspection Overview	40-11
Configuring an MGCP Inspection Policy Map for Additional Inspection Control	40-13
Configuring MGCP Timeout Values	40-14
Verifying and Monitoring MGCP Inspection	40-14
RTSP Inspection	40-15

RTSP Inspection Overview	40-15
Using RealPlayer	40-16
Restrictions and Limitations	40-16
Configuring an RTSP Inspection Policy Map for Additional Inspection Control	40-16
SIP Inspection	40-19
SIP Inspection Overview	40-19
SIP Instant Messaging	40-20
Configuring a SIP Inspection Policy Map for Additional Inspection Control	40-21
Configuring SIP Timeout Values	40-24
Verifying and Monitoring SIP Inspection	40-25
Skinny (SCCP) Inspection	40-25
SCCP Inspection Overview	40-26
Supporting Cisco IP Phones	40-26
Restrictions and Limitations	40-27
Configuring a Skinny (SCCP) Inspection Policy Map for Additional Inspection Control	40-27
Verifying and Monitoring SCCP Inspection	40-29

**CHAPTER 41****Configuring Inspection of Database and Directory Protocols 41-1**

ILS Inspection	41-1
SQL*Net Inspection	41-2
Sun RPC Inspection	41-3
Sun RPC Inspection Overview	41-3
Managing Sun RPC Services	41-4
Verifying and Monitoring Sun RPC Inspection	41-4

**CHAPTER 42****Configuring Inspection for Management Application Protocols 42-1**

DCERPC Inspection	42-1
DCERPC Overview	42-1
Configuring a DCERPC Inspection Policy Map for Additional Inspection Control	42-2
GTP Inspection	42-3
GTP Inspection Overview	42-3
Configuring a GTP Inspection Policy Map for Additional Inspection Control	42-4
Verifying and Monitoring GTP Inspection	42-8
RADIUS Accounting Inspection	42-9
RADIUS Accounting Inspection Overview	42-9
Configuring a RADIUS Inspection Policy Map for Additional Inspection Control	42-10
RSH Inspection	42-11
SNMP Inspection	42-11

SNMP Inspection Overview	42-11
Configuring an SNMP Inspection Policy Map for Additional Inspection Control	42-11
XDMCP Inspection	42-12

**PART 9****Configuring Unified Communications****CHAPTER 43****Information About Cisco Unified Communications Proxy Features** 43-1

Information About the Adaptive Security Appliance in Cisco Unified Communications	43-1
TLS Proxy Applications in Cisco Unified Communications	43-3
Licensing for Cisco Unified Communications Proxy Features	43-4

**CHAPTER 44****Configuring the Cisco Phone Proxy** 44-1

Information About the Cisco Phone Proxy	44-1
Phone Proxy Functionality	44-1
Supported Cisco UCM and IP Phones for the Phone Proxy	44-3
Licensing Requirements for the Phone Proxy	44-4
Prerequisites for the Phone Proxy	44-5
Media Termination Instance Prerequisites	44-6
Certificates from the Cisco UCM	44-6
DNS Lookup Prerequisites	44-7
Cisco Unified Communications Manager Prerequisites	44-7
Access List Rules	44-7
NAT and PAT Prerequisites	44-8
Prerequisites for IP Phones on Multiple Interfaces	44-9
7960 and 7940 IP Phones Support	44-9
Cisco IP Communicator Prerequisites	44-10
Prerequisites for Rate Limiting TFTP Requests	44-10
Rate Limiting Configuration Example	44-11
About ICMP Traffic Destined for the Media Termination Address	44-11
End-User Phone Provisioning	44-11
Ways to Deploy IP Phones to End Users	44-12
Phone Proxy Guidelines and Limitations	44-12
General Guidelines and Limitations	44-13
Media Termination Address Guidelines and Limitations	44-14
Configuring the Phone Proxy	44-14
Task Flow for Configuring the Phone Proxy in a Non-secure Cisco UCM Cluster	44-15
Importing Certificates from the Cisco UCM	44-15
Task Flow for Configuring the Phone Proxy in a Mixed-mode Cisco UCM Cluster	44-17

Creating Trustpoints and Generating Certificates	44-18
Creating the CTL File	44-19
Using an Existing CTL File	44-20
Creating the TLS Proxy Instance for a Non-secure Cisco UCM Cluster	44-21
Creating the TLS Proxy for a Mixed-mode Cisco UCM Cluster	44-21
Creating the Media Termination Instance	44-23
Creating the Phone Proxy Instance	44-24
Enabling the Phone Proxy with SIP and Skinny Inspection	44-26
Configuring Linksys Routers with UDP Port Forwarding for the Phone Proxy	44-27
Configuring Your Router	44-28
Troubleshooting the Phone Proxy	44-28
Debugging Information from the Security Appliance	44-28
Debugging Information from IP Phones	44-32
IP Phone Registration Failure	44-33
TFTP Auth Error Displays on IP Phone Console	44-33
Configuration File Parsing Error	44-34
Configuration File Parsing Error: Unable to Get DNS Response	44-34
Non-configuration File Parsing Error	44-35
Cisco UCM Does Not Respond to TFTP Request for Configuration File	44-35
IP Phone Does Not Respond After the Security Appliance Sends TFTP Data	44-36
IP Phone Requesting Unsigned File Error	44-37
IP Phone Unable to Download CTL File	44-37
IP Phone Registration Failure from Signaling Connections	44-38
SSL Handshake Failure	44-40
Certificate Validation Errors	44-41
Media Termination Address Errors	44-42
Audio Problems with IP Phones	44-42
Saving SAST Keys	44-43
Configuration Examples for the Phone Proxy	44-44
Example 1: Nonsecure Cisco UCM cluster, Cisco UCM and TFTP Server on Publisher	44-45
Example 2: Mixed-mode Cisco UCM cluster, Cisco UCM and TFTP Server on Publisher	44-46
Example 3: Mixed-mode Cisco UCM cluster, Cisco UCM and TFTP Server on Different Servers	44-47
Example 4: Mixed-mode Cisco UCM cluster, Primary Cisco UCM, Secondary and TFTP Server on Different Servers	44-49
Example 5: LSC Provisioning in Mixed-mode Cisco UCM cluster; Cisco UCM and TFTP Server on Publisher	44-51
Example 6: VLAN Transversal	44-53
Feature History for the Phone Proxy	44-55

**CHAPTER 45****Configuring the TLS Proxy for Encrypted Voice Inspection 45-1**

- Information about the TLS Proxy for Encrypted Voice Inspection 45-1
  - Decryption and Inspection of Unified Communications Encrypted Signaling 45-2
  - CTL Client Overview 45-3
- Licensing for the TLS Proxy 45-5
- Prerequisites for the TLS Proxy for Encrypted Voice Inspection 45-7
- Configuring the TLS Proxy for Encrypted Voice Inspection 45-7
  - Task flow for Configuring the TLS Proxy for Encrypted Voice Inspection 45-7
  - Creating Trustpoints and Generating Certificates 45-8
  - Creating an Internal CA 45-10
  - Creating a CTL Provider Instance 45-11
  - Creating the TLS Proxy Instance 45-12
  - Enabling the TLS Proxy Instance for Skinny or SIP Inspection 45-13
- Monitoring the TLS Proxy 45-14
- Feature History for the TLS Proxy for Encrypted Voice Inspection 45-16

**CHAPTER 46****Configuring Cisco Mobility Advantage 46-1**

- Information about the Cisco Mobility Advantage Proxy Feature 46-1
  - Cisco Mobility Advantage Proxy Functionality 46-1
  - Mobility Advantage Proxy Deployment Scenarios 46-2
    - Mobility Advantage Proxy Using NAT/PAT 46-4
  - Trust Relationships for Cisco UMA Deployments 46-5
- Licensing for the Cisco Mobility Advantage Proxy Feature 46-6
- Configuring Cisco Mobility Advantage 46-7
  - Task Flow for Configuring Cisco Mobility Advantage 46-7
  - Installing the Cisco UMA Server Certificate 46-7
  - Creating the TLS Proxy Instance 46-8
  - Enabling the TLS Proxy for MMP Inspection 46-9
- Monitoring for Cisco Mobility Advantage 46-10
- Configuration Examples for Cisco Mobility Advantage 46-11
  - Example 1: Cisco UMC/Cisco UMA Architecture – Security Appliance as Firewall with TLS Proxy and MMP Inspection 46-11
  - Example 2: Cisco UMC/Cisco UMA Architecture – Security Appliance as TLS Proxy Only 46-13
- Feature History for Cisco Mobility Advantage 46-15

**CHAPTER 47****Configuring Cisco Unified Presence 47-1**

- Information About Cisco Unified Presence 47-1
  - Architecture for Cisco Unified Presence for SIP Federation Deployments 47-1

Trust Relationship in the Presence Federation	47-4
Security Certificate Exchange Between Cisco UP and the Security Appliance	47-5
XMPP Federation Deployments	47-5
Configuration Requirements for XMPP Federation	47-6
Licensing for Cisco Unified Presence	47-7
Configuring Cisco Unified Presence Proxy for SIP Federation	47-8
Task Flow for Configuring Cisco Unified Presence Federation Proxy for SIP Federation	47-8
Creating Trustpoints and Generating Certificates	47-9
Installing Certificates	47-10
Creating the TLS Proxy Instance	47-12
Enabling the TLS Proxy for SIP Inspection	47-13
Monitoring Cisco Unified Presence	47-14
Configuration Example for Cisco Unified Presence	47-14
Example Configuration for SIP Federation Deployments	47-15
Example Access List Configuration for XMPP Federation	47-17
Example NAT Configuration for XMPP Federation	47-18
Feature History for Cisco Unified Presence	47-20

## CHAPTER 48

<b>Configuring Cisco Intercompany Media Engine Proxy</b>	<b>48-1</b>
Information About Cisco Intercompany Media Engine Proxy	48-1
Features of Cisco Intercompany Media Engine Proxy	48-1
How the UC-IME Works with the PSTN and the Internet	48-2
Tickets and Passwords	48-3
Call Fallback to the PSTN	48-5
Architecture and Deployment Scenarios for Cisco Intercompany Media Engine	48-5
Architecture	48-5
Basic Deployment	48-6
Off Path Deployment	48-7
Licensing for Cisco Intercompany Media Engine	48-8
Guidelines and Limitations	48-9
Configuring Cisco Intercompany Media Engine Proxy	48-11
Task Flow for Configuring Cisco Intercompany Media Engine	48-11
Configuring NAT for Cisco Intercompany Media Engine Proxy	48-12
Configuring PAT for the Cisco UCM Server	48-13
Creating Access Lists for Cisco Intercompany Media Engine Proxy	48-15
Creating the Media Termination Instance	48-16
Creating the Cisco Intercompany Media Engine Proxy	48-18
Creating Trustpoints and Generating Certificates	48-21
Creating the TLS Proxy	48-24

Enabling SIP Inspection for the Cisco Intercompany Media Engine Proxy	48-25
(Optional) Configuring TLS within the Local Enterprise	48-27
(Optional) Configuring Off Path Signaling	48-30
Configuring the Cisco UC-IMC Proxy by using the UC-IME Proxy Pane	48-32
Configuring the Cisco UC-IMC Proxy by using the Unified Communications Wizard	48-34
Troubleshooting Cisco Intercompany Media Engine Proxy	48-35
Feature History for Cisco Intercompany Media Engine Proxy	48-38

**PART 10****Configuring Connection Settings and QoS****CHAPTER 49****Configuring Connection Settings 49-1**

Information About Connection Settings	49-1
TCP Intercept and Limiting Embryonic Connections	49-2
Disabling TCP Intercept for Management Packets for Clientless SSL Compatibility	49-2
Dead Connection Detection (DCD)	49-2
TCP Sequence Randomization	49-3
TCP Normalization	49-3
TCP State Bypass	49-3
Licensing Requirements for Connection Settings	49-4
Guidelines and Limitations	49-5
TCP State Bypass Guidelines and Limitations	49-5
Default Settings	49-5
Configuring Connection Settings	49-6
Task Flow For Configuring Configuration Settings (Except Global Timeouts)	49-6
Customizing the TCP Normalizer with a TCP Map	49-6
Configuring Connection Settings	49-11
Monitoring Connection Settings	49-15
Monitoring TCP State Bypass	49-15
Configuration Examples for Connection Settings	49-15
Configuration Examples for Connection Limits and Timeouts	49-16
Configuration Examples for TCP State Bypass	49-16
Configuration Examples for TCP Normalization	49-16
Feature History for Connection Settings	49-17

**CHAPTER 50****Configuring QoS 50-1**

Information About QoS	50-1
Supported QoS Features	50-2
What is a Token Bucket?	50-2

Information About Policing	50-3
Information About Priority Queuing	50-3
Information About Traffic Shaping	50-4
How QoS Features Interact	50-4
DSCP and DiffServ Preservation	50-5
Licensing Requirements for QoS	50-5
Guidelines and Limitations	50-5
Configuring QoS	50-6
Determining the Queue and TX Ring Limits for a Standard Priority Queue	50-6
Configuring the Standard Priority Queue for an Interface	50-7
Configuring a Service Rule for Standard Priority Queuing and Policing	50-9
Configuring a Service Rule for Traffic Shaping and Hierarchical Priority Queuing	50-12
(Optional) Configuring the Hierarchical Priority Queuing Policy	50-12
Configuring the Service Rule	50-13
Monitoring QoS	50-15
Viewing QoS Police Statistics	50-15
Viewing QoS Standard Priority Statistics	50-16
Viewing QoS Shaping Statistics	50-16
Viewing QoS Standard Priority Queue Statistics	50-17
Feature History for QoS	50-18

## PART 11

## Configuring Advanced Network Protection

### CHAPTER 51

## Configuring the Botnet Traffic Filter 51-1

Information About the Botnet Traffic Filter	51-1
Botnet Traffic Filter Address Categories	51-2
Botnet Traffic Filter Actions for Known Addresses	51-2
Botnet Traffic Filter Databases	51-2
Information About the Dynamic Database	51-2
Information About the Static Database	51-3
Information About the DNS Reverse Lookup Cache and DNS Host Cache	51-3
How the Botnet Traffic Filter Works	51-4
Licensing Requirements for the Botnet Traffic Filter	51-5
Guidelines and Limitations	51-5
Default Settings	51-6
Configuring the Botnet Traffic Filter	51-6
Task Flow for Configuring the Botnet Traffic Filter	51-6
Configuring the Dynamic Database	51-7

Adding Entries to the Static Database	51-8
Enabling DNS Snooping	51-9
Enabling Traffic Classification and Actions for the Botnet Traffic Filter	51-11
Blocking Botnet Traffic Manually	51-14
Searching the Dynamic Database	51-15
Monitoring the Botnet Traffic Filter	51-16
Botnet Traffic Filter Syslog Messaging	51-16
Botnet Traffic Filter Commands	51-16
Configuration Examples for the Botnet Traffic Filter	51-18
Recommended Configuration Example	51-18
Other Configuration Examples	51-19
Where to Go Next	51-20
Feature History for the Botnet Traffic Filter	51-21

## CHAPTER 52

### Configuring Threat Detection 52-1

Information About Threat Detection	52-1
Configuring Basic Threat Detection Statistics	52-1
Information About Basic Threat Detection Statistics	52-2
Guidelines and Limitations	52-2
Default Settings	52-3
Configuring Basic Threat Detection Statistics	52-4
Monitoring Basic Threat Detection Statistics	52-5
Feature History for Basic Threat Detection Statistics	52-6
Configuring Advanced Threat Detection Statistics	52-6
Information About Advanced Threat Detection Statistics	52-6
Guidelines and Limitations	52-6
Default Settings	52-7
Configuring Advanced Threat Detection Statistics	52-7
Monitoring Advanced Threat Detection Statistics	52-9
Feature History for Advanced Threat Detection Statistics	52-13
Configuring Scanning Threat Detection	52-14
Information About Scanning Threat Detection	52-14
Guidelines and Limitations	52-15
Default Settings	52-15
Configuring Scanning Threat Detection	52-16
Monitoring Shunned Hosts, Attackers, and Targets	52-16
Feature History for Scanning Threat Detection	52-17
Configuration Examples for Threat Detection	52-18

---

**CHAPTER 53**

**Using Protection Tools 53-1**

- Preventing IP Spoofing 53-1
- Configuring the Fragment Size 53-2
- Blocking Unwanted Connections 53-2
- Configuring IP Audit for Basic IPS Support 53-3
  - Configuring IP Audit 53-3
  - IP Audit Signature List 53-4

---

**PART 12**

**Configuring Applications on Modules**

---

**CHAPTER 54**

**Managing Service Modules 54-1**

- Information About Modules 54-1
  - Supported Applications 54-2
  - Information About Management Access 54-2
    - Sessioning to the Module 54-2
    - Using ASDM 54-2
    - Using SSH or Telnet 54-3
    - Other Uses for the Module Management Interface 54-3
    - Routing Considerations for Accessing the Management Interface 54-3
- Guidelines and Limitations 54-3
- Default Settings 54-4
- Configuring the SSC Management Interface 54-5
- Sessioning to the Module 54-7
- Troubleshooting the Module 54-7
  - Management IP Address Troubleshooting 54-8
  - TFTP Troubleshooting 54-8
  - Installing an Image on the Module 54-8
  - Password Troubleshooting 54-9
  - Reloading or Resetting the Module 54-10
  - Shutting Down the Module 54-10
- Monitoring Modules 54-11
- Where to Go Next 54-12
- Feature History for Modules 54-12

---

**CHAPTER 55**

**Configuring the IPS Module 55-1**

- Information About the IPS Module 55-1
  - How the IPS Module Works with the Adaptive Security Appliance 55-1
  - Operating Modes 55-2

Using Virtual Sensors (ASA 5510 and Higher)	55-3
Differences Between the Modules	55-4
Licensing Requirements for the IPS Module	55-4
Guidelines and Limitations	55-4
Configuring the IPS Module	55-5
IPS Module Task Overview	55-5
Configuring the Security Policy on the IPS Module	55-5
Assigning Virtual Sensors to a Security Context (ASA 5510 and Higher)	55-6
Diverting Traffic to the IPS Module	55-8
Monitoring the IPS Module	55-10
Configuration Examples for the IPS Module	55-10
Feature History for the IPS Module	55-11

---

**CHAPTER 56**
**Configuring the Content Security and Control Application on the CSC SSM 56-1**

Information About the CSC SSM	56-1
Determining What Traffic to Scan	56-3
Licensing Requirements for the CSC SSM	56-5
Prerequisites for the CSC SSM	56-5
Guidelines and Limitations	56-6
Default Settings	56-6
Configuring the CSC SSM	56-7
Before Configuring the CSC SSM	56-7
Connecting to the CSC SSM	56-8
Diverting Traffic to the CSC SSM	56-10
Monitoring the CSC SSM	56-13
Configuration Examples for the CSC SSM	56-13
Where to Go Next	56-15
Additional References	56-15
Feature History for the CSC SSM	56-15

---

**PART 13**
**Configuring High Availability**

---

**CHAPTER 57**
**Information About High Availability 57-1**

Information About Failover and High Availability	57-1
Failover System Requirements	57-2
Hardware Requirements	57-2
Software Requirements	57-2

License Requirements	57-2
Failover and Stateful Failover Links	57-3
Failover Link	57-3
Stateful Failover Link	57-4
Failover Interface Speed for Stateful Links	57-4
Avoiding Interrupted Failover Links	57-5
Active/Active and Active/Standby Failover	57-9
Determining Which Type of Failover to Use	57-9
Stateless (Regular) and Stateful Failover	57-10
Stateless (Regular) Failover	57-10
Stateful Failover	57-10
Transparent Firewall Mode Requirements	57-11
Auto Update Server Support in Failover Configurations	57-12
Auto Update Process Overview	57-12
Monitoring the Auto Update Process	57-13
Failover Health Monitoring	57-15
Unit Health Monitoring	57-15
Interface Monitoring	57-15
Failover Feature/Platform Matrix	57-16
Failover Times by Platform	57-16
Failover Messages	57-17
Failover System Messages	57-17
Debug Messages	57-17
SNMP	57-17

**CHAPTER 58****Configuring Active/Active Failover 58-1**

Information About Active/Active Failover	58-1
Active/Active Failover Overview	58-1
Primary/Secondary Status and Active/Standby Status	58-2
Device Initialization and Configuration Synchronization	58-3
Command Replication	58-3
Failover Triggers	58-5
Failover Actions	58-5
Optional Active/Active Failover Settings	58-6
Licensing Requirements for Active/Active Failover	58-6
Prerequisites for Active/Active Failover	58-7
Guidelines and Limitations	58-7
Configuring Active/Active Failover	58-8

Task Flow for Configuring Active/Active Failover	58-8
Configuring the Primary Failover Unit	58-9
Configuring the Secondary Failover Unit	58-12
Configuring Optional Active/Active Failover Settings	58-13
Configuring Failover Group Preemption	58-14
Enabling HTTP Replication with Stateful Failover	58-15
Disabling and Enabling Interface Monitoring	58-15
Configuring Interface Health Monitoring	58-16
Configuring Failover Criteria	58-17
Configuring Virtual MAC Addresses	58-17
Configuring Support for Asymmetrically Routed Packets	58-19
Remote Command Execution	58-22
Changing Command Modes	58-23
Security Considerations	58-24
Limitations of Remote Command Execution	58-24
Controlling Failover	58-24
Forcing Failover	58-25
Disabling Failover	58-25
Restoring a Failed Unit or Failover Group	58-25
Testing the Failover Functionality	58-25
Monitoring Active/Active Failover	58-26
Feature History for Active/Active Failover	58-26

## CHAPTER 59

### Configuring Active/Standby Failover 59-1

Information About Active/Standby Failover	59-1
Active/Standby Failover Overview	59-1
Primary/Secondary Status and Active/Standby Status	59-2
Device Initialization and Configuration Synchronization	59-2
Command Replication	59-3
Failover Triggers	59-4
Failover Actions	59-4
Optional Active/Standby Failover Settings	59-5
Licensing Requirements for Active/Standby Failover	59-5
Prerequisites for Active/Standby Failover	59-6
Guidelines and Limitations	59-6
Configuring Active/Standby Failover	59-7
Task Flow for Configuring Active/Standby Failover	59-7
Configuring the Primary Unit	59-7
Configuring the Secondary Unit	59-10

Configuring Optional Active/Standby Failover Settings	59-11
Enabling HTTP Replication with Stateful Failover	59-11
Disabling and Enabling Interface Monitoring	59-12
Configuring Failover Criteria	59-13
Configuring the Unit and Interface Health Poll Times	59-13
Configuring Virtual MAC Addresses	59-14
Controlling Failover	59-15
Forcing Failover	59-16
Disabling Failover	59-16
Restoring a Failed Unit	59-16
Testing the Failover Functionality	59-17
Monitoring Active/Standby Failover	59-17
Feature History for Active/Standby Failover	59-17

---

**PART 14**

---

**Configuring VPN**

---

**CHAPTER 60**

---

**Configuring IPsec and ISAKMP 60-1**

Information About Tunneling, IPsec, and ISAKMP	60-1
IPsec Overview	60-2
Licensing Requirements for Remote Access IPsec VPNs	60-2
Guidelines and Limitations	60-2
Configuring ISAKMP	60-3
ISAKMP Overview	60-3
Configuring ISAKMP Policies	60-6
Enabling ISAKMP on the Outside Interface	60-7
Disabling ISAKMP in Aggressive Mode	60-7
Determining an ID Method for ISAKMP Peers	60-7
Enabling IPsec over NAT-T	60-8
Using NAT-T	60-9
Enabling IPsec over TCP	60-9
Waiting for Active Sessions to Terminate Before Rebooting	60-10
Alerting Peers Before Disconnecting	60-10
Configuring Certificate Group Matching	60-10
Creating a Certificate Group Matching Rule and Policy	60-11
Using the Tunnel-group-map default-group Command	60-12
Configuring IPsec	60-12
Understanding IPsec Tunnels	60-13
Understanding Transform Sets	60-13

Defining Crypto Maps	60-13
Applying Crypto Maps to Interfaces	60-21
Using Interface Access Lists	60-21
Changing IPsec SA Lifetimes	60-23
Creating a Basic IPsec Configuration	60-24
Using Dynamic Crypto Maps	60-25
Providing Site-to-Site Redundancy	60-28
Viewing an IPsec Configuration	60-28
Clearing Security Associations	60-28
Clearing Crypto Map Configurations	60-29
Supporting the Nokia VPN Client	60-29

## CHAPTER 61

### Configuring L2TP over IPsec 61-1

Information About L2TP over IPsec	61-1
IPsec Transport and Tunnel Modes	61-2
Licensing Requirements for L2TP over IPsec	61-3
Guidelines and Limitations	61-3
Configuring L2TP over IPsec	61-4
Configuration Examples for L2TP over IPsec	61-8
Feature History for L2TP over IPsec	61-8

## CHAPTER 62

### Setting General VPN Parameters 62-1

Configuring VPNs in Single, Routed Mode	62-1
Configuring IPsec to Bypass ACLs	62-1
Permitting Intra-Interface Traffic (Hairpinning)	62-2
NAT Considerations for Intra-Interface Traffic	62-3
Setting Maximum Active IPsec or SSL VPN Sessions	62-4
Using Client Update to Ensure Acceptable IPsec Client Revision Levels	62-4
Understanding Load Balancing	62-6
Comparing Load Balancing to Failover	62-7
Load Balancing	62-7
Failover	62-7
Implementing Load Balancing	62-8
Prerequisites	62-8
Eligible Platforms	62-8
Eligible Clients	62-8
VPN Load Balancing Algorithm	62-9
VPN Load-Balancing Cluster Configurations	62-9

Some Typical Mixed Cluster Scenarios	62-10
Scenario 1: Mixed Cluster with No SSL VPN Connections	62-10
Scenario 2: Mixed Cluster Handling SSL VPN Connections	62-10

## **Configuring Load Balancing** 62-11

Configuring the Public and Private Interfaces for Load Balancing	62-11
Configuring the Load Balancing Cluster Attributes	62-12
Enabling Redirection Using a Fully-qualified Domain Name	62-13
Frequently Asked Questions About Load Balancing	62-14
IP Address Pool Exhaustion	62-14
Unique IP Address Pools	62-14
Using Load Balancing and Failover on the Same Device	62-14
Load Balancing on Multiple Interfaces	62-15
Maximum Simultaneous Sessions for Load Balancing Clusters	62-15
Viewing Load Balancing	62-15
Configuring VPN Session Limits	62-16

## **CHAPTER 63**

## **Configuring Connection Profiles, Group Policies, and Users** 63-1

Overview of Connection Profiles, Group Policies, and Users	63-1
Connection Profiles	63-2
General Connection Profile Connection Parameters	63-3
IPSec Tunnel-Group Connection Parameters	63-4
Connection Profile Connection Parameters for SSL VPN Sessions	63-5
Configuring Connection Profiles	63-6
Maximum Connection Profiles	63-6
Default IPSec Remote Access Connection Profile Configuration	63-7
Configuring IPSec Tunnel-Group General Attributes	63-7
Configuring IPSec Remote-Access Connection Profiles	63-7
Specifying a Name and Type for the IPSec Remote Access Connection Profile	63-8
Configuring IPSec Remote-Access Connection Profile General Attributes	63-8
Configuring Double Authentication	63-12
Enabling IPv6 VPN Access	63-13
Configuring IPSec Remote-Access Connection Profile IPSec Attributes	63-15
Configuring IPSec Remote-Access Connection Profile PPP Attributes	63-17
Configuring LAN-to-LAN Connection Profiles	63-18
Default LAN-to-LAN Connection Profile Configuration	63-18
Specifying a Name and Type for a LAN-to-LAN Connection Profile	63-18
Configuring LAN-to-LAN Connection Profile General Attributes	63-18
Configuring LAN-to-LAN IPSec Attributes	63-19
Configuring Connection Profiles for Clientless SSL VPN Sessions	63-21

Specifying a Connection Profile Name and Type for Clientless SSL VPN Sessions	63-21
Configuring General Tunnel-Group Attributes for Clientless SSL VPN Sessions	63-21
Configuring Tunnel-Group Attributes for Clientless SSL VPN Sessions	63-24
Customizing Login Windows for Users of Clientless SSL VPN sessions	63-29
Configuring Microsoft Active Directory Settings for Password Management	63-29
Using Active Directory to Force the User to Change Password at Next Logon	63-30
Using Active Directory to Specify Maximum Password Age	63-32
Using Active Directory to Override an Account Disabled AAA Indicator	63-33
Using Active Directory to Enforce Minimum Password Length	63-34
Using Active Directory to Enforce Password Complexity	63-35
Configuring the Connection Profile for RADIUS/SDI Message Support for the AnyConnect Client	63-36
AnyConnect Client and RADIUS/SDI Server Interaction	63-36
Configuring the Security Appliance to Support RADIUS/SDI Messages	63-37
Group Policies	63-38
Default Group Policy	63-39
Configuring Group Policies	63-40
Configuring an External Group Policy	63-41
Configuring an Internal Group Policy	63-41
Configuring Group Policy Attributes	63-42
Configuring WINS and DNS Servers	63-42
Configuring VPN-Specific Attributes	63-43
Configuring Security Attributes	63-47
Configuring the Banner Message	63-49
Configuring IPSec-UDP Attributes	63-50
Configuring Split-Tunneling Attributes	63-50
Configuring Domain Attributes for Tunneling	63-52
Configuring Attributes for VPN Hardware Clients	63-53
Configuring Backup Server Attributes	63-57
Configuring Microsoft Internet Explorer Client Parameters	63-58
Configuring Network Admission Control Parameters	63-60
Configuring Address Pools	63-63
Configuring Firewall Policies	63-64
Supporting a Zone Labs Integrity Server	63-65
Overview of the Integrity Server and Adaptive Security Appliance Interaction	63-65
Configuring Integrity Server Support	63-66
Setting Up Client Firewall Parameters	63-67
Configuring Client Access Rules	63-69
Configuring Group-Policy Attributes for Clientless SSL VPN Sessions	63-71
Configuring User Attributes	63-81

Viewing the Username Configuration	63-82
Configuring Attributes for Specific Users	63-82
Setting a User Password and Privilege Level	63-82
Configuring User Attributes	63-83
Configuring VPN User Attributes	63-83
Configuring Clientless SSL VPN Access for Specific Users	63-87

**CHAPTER 64****Configuring IP Addresses for VPNs 64-1**

Configuring an IP Address Assignment Method	64-1
Configuring Local IP Address Pools	64-2
Configuring AAA Addressing	64-2
Configuring DHCP Addressing	64-3

**CHAPTER 65****Configuring Remote Access IPsec VPNs 65-1**

Information About Remote Access IPsec VPNs	65-1
Licensing Requirements for Remote Access IPsec VPNs	65-2
Guidelines and Limitations	65-2
Configuring Remote Access IPsec VPNs	65-2
Configuring Interfaces	65-3
Configuring ISAKMP Policy and Enabling ISAKMP on the Outside Interface	65-4
Configuring an Address Pool	65-5
Adding a User	65-5
Creating a Transform Set	65-6
Defining a Tunnel Group	65-6
Creating a Dynamic Crypto Map	65-7
Creating a Crypto Map Entry to Use the Dynamic Crypto Map	65-8
Saving the Security Appliance Configuration	65-9
Configuration Examples for Remote Access IPsec VPNs	65-9
Feature History for Remote Access IPsec VPNs	65-10

**CHAPTER 66****Configuring Network Admission Control 66-1**

Overview	66-1
Uses, Requirements, and Limitations	66-2
Viewing the NAC Policies on the Security Appliance	66-2
Adding, Accessing, or Removing a NAC Policy	66-4
Configuring a NAC Policy	66-4
Specifying the Access Control Server Group	66-5
Setting the Query-for-Posture-Changes Timer	66-5

Setting the Revalidation Timer	66-6
Configuring the Default ACL for NAC	66-6
Configuring Exemptions from NAC	66-7
Assigning a NAC Policy to a Group Policy	66-8
Changing Global NAC Framework Settings	66-8
Changing Clientless Authentication Settings	66-8
Enabling and Disabling Clientless Authentication	66-8
Changing the Login Credentials Used for Clientless Authentication	66-9
Changing NAC Framework Session Attributes	66-10

---

**CHAPTER 67**

<b>Configuring Easy VPN Services on the ASA 5505</b>	67-1
Specifying the Client/Server Role of the Cisco ASA 5505	67-1
Specifying the Primary and Secondary Servers	67-2
Specifying the Mode	67-3
NEM with Multiple Interfaces	67-3
Configuring Automatic Xauth Authentication	67-4
Configuring IPSec Over TCP	67-4
Comparing Tunneling Options	67-5
Specifying the Tunnel Group or Trustpoint	67-6
Specifying the Tunnel Group	67-7
Specifying the Trustpoint	67-7
Configuring Split Tunneling	67-8
Configuring Device Pass-Through	67-8
Configuring Remote Management	67-9
Guidelines for Configuring the Easy VPN Server	67-10
Group Policy and User Attributes Pushed to the Client	67-10
Authentication Options	67-12

---

**CHAPTER 68**

<b>Configuring the PPPoE Client</b>	68-1
PPPoE Client Overview	68-1
Configuring the PPPoE Client Username and Password	68-2
Enabling PPPoE	68-3
Using PPPoE with a Fixed IP Address	68-3
Monitoring and Debugging the PPPoE Client	68-4
Clearing the Configuration	68-5
Using Related Commands	68-5

**CHAPTER 69****Configuring LAN-to-LAN IPsec VPNs 69-1**

- Summary of the Configuration 69-2
- Configuring Interfaces 69-2
- Configuring ISAKMP Policy and Enabling ISAKMP on the Outside Interface 69-3
- Creating a Transform Set 69-4
- Configuring an ACL 69-5
- Defining a Tunnel Group 69-6
- Creating a Crypto Map and Applying It To an Interface 69-7
  - Applying Crypto Maps to Interfaces 69-8

**CHAPTER 70****Configuring Clientless SSL VPN 70-1**

- Getting Started 70-1
  - Observing Clientless SSL VPN Security Precautions 70-2
  - Understanding Clientless SSL VPN System Requirements 70-3
  - Understanding Features Not Supported in Clientless SSL VPN 70-4
  - Using SSL to Access the Central Site 70-4
    - Using HTTPS for Clientless SSL VPN Sessions 70-4
    - Configuring Clientless SSL VPN and ASDM Ports 70-5
    - Configuring Support for Proxy Servers 70-5
    - Configuring SSL/TLS Encryption Protocols 70-7
  - Authenticating with Digital Certificates 70-7
  - Enabling Cookies on Browsers for Clientless SSL VPN 70-7
  - Managing Passwords 70-8
  - Using Single Sign-on with Clientless SSL VPN 70-9
    - Configuring SSO with HTTP Basic or NTLM Authentication 70-9
    - Configuring SSO Authentication Using SiteMinder 70-11
    - Configuring SSO Authentication Using SAML Browser Post Profile 70-13
    - Configuring SSO with the HTTP Form Protocol 70-16
    - Configuring SSO for Plug-ins 70-22
    - Configuring SSO with Macro Substitution 70-22
  - Authenticating with Digital Certificates 70-23
- Creating and Applying Clientless SSL VPN Policies for Accessing Resources 70-23
  - Assigning Users to Group Policies 70-23
    - Using the Security Appliance Authentication Server 70-24
    - Using a RADIUS Server 70-24
    - Using an LDAP Server 70-24
- Configuring Connection Profile Attributes for Clientless SSL VPN 70-24
- Configuring Group Policy and User Attributes for Clientless SSL VPN 70-25

Configuring Browser Access to Plug-ins	70-26
Introduction to Browser Plug-Ins	70-27
RDP Plug-in ActiveX Debug Quick Reference	70-27
Plug-in Requirements and Restrictions	70-28
Single Sign-On for Plug-ins	70-28
Preparing the Security Appliance for a Plug-in	70-28
Installing Plug-ins Redistributed By Cisco	70-29
Providing Access to Third-Party Plug-ins	70-31
Example: Providing Access to a Citrix Java Presentation Server	70-31
Viewing the Plug-ins Installed on the Security Appliance	70-32
Configuring Application Access	70-33
Configuring Smart Tunnel Access	70-33
About Smart Tunnels	70-34
Why Smart Tunnels?	70-34
Smart Tunnel Requirements, Restrictions, and Limitations	70-34
Adding Applications to Be Eligible for Smart Tunnel Access	70-36
Assigning a Smart Tunnel List	70-39
Configuring Smart Tunnel Policy	70-40
Applying the Tunnel Policy	70-40
Configuring a Smart Tunnel Tunnel Policy	70-40
Applying Smart Tunnel Tunnel Policy	70-40
Configuring Smart Tunnel Auto Sign-on	70-41
Automating Smart Tunnel Access	70-43
Enabling and Disabling Smart Tunnel Access	70-44
Logging Off Smart Tunnel	70-44
Parent Affinity	70-44
Notification Icon	70-45
Configuring Port Forwarding	70-45
About Port Forwarding	70-46
Why Port Forwarding?	70-46
Port Forwarding Requirements and Restrictions	70-46
Configuring DNS for Port Forwarding	70-47
Adding Applications to Be Eligible for Port Forwarding	70-48
Assigning a Port Forwarding List	70-49
Automating Port Forwarding	70-50
Enabling and Disabling Port Forwarding	70-50
Application Access User Notes	70-51
Using Application Access on Vista	70-51
Closing Application Access to Prevent hosts File Errors	70-51
Recovering from hosts File Errors When Using Application Access	70-51

Configuring File Access	70-54
CIFS File Access Requirement and Limitation	70-55
Adding Support for File Access	70-55
Ensuring Clock Accuracy for SharePoint Access	70-56
Using Clientless SSL VPN with PDAs	70-56
Using E-Mail over Clientless SSL VPN	70-57
Configuring E-mail Proxies	70-57
E-mail Proxy Certificate Authentication	70-58
Configuring Web E-mail: MS Outlook Web Access	70-58
Optimizing Clientless SSL VPN Performance	70-59
Configuring Caching	70-59
Configuring Content Transformation	70-59
Configuring a Certificate for Signing Rewritten Java Content	70-60
Disabling Content Rewrite	70-60
Using Proxy Bypass	70-60
Configuring Application Profile Customization Framework	70-61
APCF Syntax	70-61
Clientless SSL VPN End User Setup	70-64
Defining the End User Interface	70-64
Viewing the Clientless SSL VPN Home Page	70-65
Viewing the Clientless SSL VPN Application Access Panel	70-65
Viewing the Floating Toolbar	70-66
Customizing Clientless SSL VPN Pages	70-67
How Customization Works	70-67
Exporting a Customization Template	70-68
Editing the Customization Template	70-68
Importing a Customization Object	70-74
Applying Customizations to Connection Profiles, Group Policies and Users	70-74
Login Screen Advanced Customization	70-75
Customizing Help	70-79
Customizing a Help File Provided By Cisco	70-80
Creating Help Files for Languages Not Provided by Cisco	70-81
Importing a Help File to Flash Memory	70-81
Exporting a Previously Imported Help File from Flash Memory	70-82
Requiring Usernames and Passwords	70-82
Communicating Security Tips	70-83
Configuring Remote Systems to Use Clientless SSL VPN Features	70-83
Translating the Language of User Messages	70-88
Understanding Language Translation	70-88

Creating Translation Tables	70-89
Referencing the Language in a Customization Object	70-90
Changing a Group Policy or User Attributes to Use the Customization Object	70-92
Capturing Data	70-92
Creating a Capture File	70-92
Using a Browser to Display Capture Data	70-93

### System Administration

## CHAPTER 76

<b>Managing Software and Configurations</b>	76-1
Viewing Files in Flash Memory	76-1
Retrieving Files from Flash Memory	76-2
Removing Files from Flash Memory	76-2
Copying Files to a Local File System on a UNIX Server	76-2
Downloading Software or Configuration Files to Flash Memory	76-3
Downloading a File to a Specific Location	76-3

Downloading a File to the Startup or Running Configuration	76-4
Configuring the Application Image and ASDM Image to Boot	76-5
Configuring the File to Boot as the Startup Configuration	76-5
Performing Zero Downtime Upgrades for Failover Pairs	76-6
Upgrading an Active/Standby Failover Configuration	76-6
Upgrading an Active/Active Failover Configuration	76-7
Backing Up Configuration Files	76-8
Backing up the Single Mode Configuration or Multiple Mode System Configuration	76-8
Backing Up a Context Configuration in Flash Memory	76-8
Backing Up a Context Configuration within a Context	76-9
Copying the Configuration from the Terminal Display	76-9
Backing Up Additional Files Using the Export and Import Commands	76-9
Using a Script to Back Up and Restore Files	76-10
Prerequisites	76-10
Running the Script	76-10
Sample Script	76-11
Downgrading Your Software	76-16
Information About Activation Key Compatibility	76-16
Performing the Downgrade	76-16
Configuring Auto Update Support	76-17
Configuring Communication with an Auto Update Server	76-18
Configuring Client Updates as an Auto Update Server	76-19
Viewing Auto Update Status	76-20

## CHAPTER 77

## Troubleshooting 77-1

Testing Your Configuration	77-1
Enabling ICMP Debugging Messages and Syslog Messages	77-2
Pinging Adaptive Security Appliance Interfaces	77-2
Passing Traffic Through the Adaptive Security Appliance	77-4
Disabling the Test Configuration	77-5
Determining Packet Routing with Traceroute	77-6
Tracing Packets with Packet Tracer	77-6
Reloading the Adaptive Security Appliance	77-6
Performing Password Recovery	77-7
Recovering Passwords for the ASA 5500 Series Adaptive Security Appliance	77-7
Disabling Password Recovery	77-8
Resetting the Password on the SSM Hardware Module	77-9
Using the ROM Monitor to Load a Software Image	77-9

Erasing the Flash File System	77-11
Other Troubleshooting Tools	77-11
Viewing Debugging Messages	77-11
Capturing Packets	77-11
Viewing the Crash Dump	77-12
Coredump	77-12
Common Problems	77-12

**GLOSSARY**

---

**INDEX**

## About This Guide

---

This preface introduces *Cisco ASA 5500 Series Configuration Guide using the CLI* and includes the following sections:

- [Document Objectives, page lix](#)
- [Audience, page lix](#)
- [Related Documentation, page lx](#)
- [Document Conventions, page lx](#)
- [Obtaining Documentation, Obtaining Support, and Security Guidelines, page lx](#)

## Document Objectives

The purpose of this guide is to help you configure the adaptive security appliance using the command-line interface. This guide does not cover every feature, but describes only the most common configuration scenarios.

You can also configure and monitor the adaptive security appliance by using ASDM, a web-based GUI application. ASDM includes configuration wizards to guide you through some common configuration scenarios, and online help for less common scenarios.

This guide applies to the Cisco ASA 5500 series adaptive security appliances. Throughout this guide, the term “adaptive security appliance” applies generically to all supported models, unless specified otherwise. The PIX 500 security appliances are not supported.

## Audience

This guide is for network managers who perform any of the following tasks:

- Manage network security
- Install and configure firewalls/adaptive security appliances
- Configure VPNs
- Configure intrusion detection software

## Related Documentation

For more information, see *Navigating the Cisco ASA 5500 Series Documentation* at <http://www.cisco.com/en/US/docs/security/asa/roadmap/asaroadmap.html>.

## Document Conventions

Command descriptions use these conventions:

- Braces ( { } ) indicate a required choice.
- Square brackets ( [ ] ) indicate optional elements.
- Vertical bars ( | ) separate alternative, mutually exclusive elements.
- **Boldface** indicates commands and keywords that are entered literally as shown.
- *Italics* indicate arguments for which you supply values.

Examples use these conventions:

- Examples depict screen displays and the command line in `screen` font.
- Information you need to enter in examples is shown in **boldface screen** font.
- Variables for which you must supply a value are shown in *italic screen* font.

### Note

Means *reader take note*. Notes contain helpful suggestions or references to material not covered in the manual.

## Obtaining Documentation, Obtaining Support, and Security Guidelines

For information on obtaining documentation, obtaining support, providing documentation feedback, security guidelines, and also recommended aliases and general Cisco documents, see the monthly *What's New in Cisco Product Documentation*, which also lists all new and revised Cisco technical documentation, at:

<http://www.cisco.com/en/US/docs/general/whatsnew/whatsnew.html>

## **PART 1**

### **Getting Started and General Information**

# CHAPTER 1

## Introduction to the Cisco ASA 5500 Series Adaptive Security Appliance

---

The adaptive security appliance combines advanced stateful firewall and VPN concentrator functionality in one device, and for some models, an integrated intrusion prevention module called the AIP SSM/SSC or an integrated content security and control module called the CSC SSM. The adaptive security appliance includes many advanced features, such as multiple security contexts (similar to virtualized firewalls), transparent (Layer 2) firewall or routed (Layer 3) firewall operation, advanced inspection engines, IPSec VPN, SSL VPN, and clientless SSL VPN support, and many more features.

This chapter includes the following sections:

- [ASA 5500 Model Support, page 1-1](#)
- [Module Support, page 1-1](#)
- [VPN Specifications, page 1-2](#)
- [New Features, page 1-2](#)
- [Firewall Functional Overview, page 1-10](#)
- [VPN Functional Overview, page 1-15](#)
- [Security Context Overview, page 1-15](#)

## ASA 5500 Model Support

For a complete list of supported ASA models for this release, see *Cisco ASA 5500 Series Hardware and Software Compatibility*:

<http://www.cisco.com/en/US/docs/security/asa/compatibility/asamatrix.html>

## Module Support

For a complete list of supported modules for this release, see *Cisco ASA 5500 Series Hardware and Software Compatibility*:

<http://www.cisco.com/en/US/docs/security/asa/compatibility/asamatrix.html>

# VPN Specifications

See the *Supported VPN Platforms, Cisco ASA 5500 Series*:

<http://www.cisco.com/en/US/docs/security/asa/compatibility/vpn-platforms-83.html>.

## New Features

- This section includes the following topics: [New Features in Version 8.3\(2\), page 1-3](#)
- [New Features in Version 8.3\(1\), page 1-5](#)

### Note

New, changed, and deprecated syslog messages are listed in *Cisco ASA 5500 Series System Log Messages*.

**Table 1-1**      **New Features for ASA Version 8.2(3)**

Feature	Description
<b>Hardware Features</b>	
Support for the Cisco ASA 5585-X with SSP-20 and SSP-60	Support for the ASA 5585-X with Security Services Processor (SSP)-20 and -60 was introduced. <b>Note</b> The ASA 5585-X is not supported in Version 8.3(x).
<b>Remote Access Features</b>	
Hardware processing for large modulus operations (2048-bit RSA certificate and DH5)	<p>This feature lets you switch large modulus operations from software to hardware. It applies only to the ASA models 5510, 5520, 5540, and 5550.</p> <p>The switch to hardware accelerates the following:</p> <ul style="list-style-type: none"> <li>• 2048-bit RSA public key certificate processing.</li> <li>• Diffie Hellman Group 5 key generation.</li> </ul> <p>We recommend that you enable this feature if it is necessary to improve the connections per second. Depending on the load, it might have a limited performance impact on SSL throughput. We recommend that you use this feature during a low-use or maintenance period to minimize a temporary packet loss that can occur during the transition of processing from software to hardware.</p> <p>The following commands were introduced or modified: <b>crypto engine large-mod-accel</b>, <b>clear configure crypto engine</b>, <b>show running-config crypto engine</b>, and <b>show running-config crypto</b>.</p>

**Table 1-1**      ***New Features for ASA Version 8.2(3) (continued)***

Feature	Description
Microsoft Internet Explorer proxy lockdown control	<p>Enabling this feature hides the Connections tab in Microsoft Internet Explorer for the duration of an AnyConnect VPN session. Disabling the feature leaves the display of the Connections tab unchanged; the default setting for the tab can be shown or hidden, depending on the user registry settings.</p> <p>The following command was introduced: <b>msie-proxy lockdown</b>.</p>
Trusted Network Detection Pause and Resume	<p>This feature enables the AnyConnect client to retain its session information and cookie so that it can seamlessly restore connectivity after the user leaves the office, as long as the session does not exceed the idle timer setting. This feature requires an AnyConnect release that supports TND pause and resume.</p>

## New Features in Version 8.3(2)

Table 1-2 lists the new features for ASA Version 8.3(2).

**Table 1-2**      ***New Features for ASA Version 8.3(2)***

Feature	Description
<b>Monitoring Features</b>	
Enhanced logging and connection blocking	<p>When you configure a syslog server to use TCP, and the syslog server is unavailable, the adaptive security appliance blocks new connections that generate syslog messages until the server becomes available again (for example, VPN, firewall, and cut-through-proxy connections). This feature has been enhanced to also block new connections when the logging queue on the adaptive security appliance is full; connections resume when the logging queue is cleared.</p> <p>This feature was added for compliance with Common Criteria EAL4+. Unless required, we recommend allowing new connections when syslog messages cannot be sent. To allow new connections, configure the syslog server to use UDP or use the <b>logging permit-hostdown</b> command.</p> <p>The following commands were modified: <b>show logging</b>.</p> <p>The following syslog messages were introduced: 414005, 414006, 414007, and 414008</p>
<b>Remote Access Features</b>	

**Table 1-2**      ***New Features for ASA Version 8.3(2) (continued)***

Feature	Description
Hardware processing for large modulus operations (2048-bit RSA certificate and DH5)	<p>This feature lets you switch large modulus operations from software to hardware. It applies only to the ASA models 5510, 5520, 5540, and 5550.</p> <p>The switch to hardware accelerates the following:</p> <ul style="list-style-type: none"> <li>• 2048-bit RSA public key certificate processing.</li> <li>• Diffie Hellman Group 5 key generation.</li> </ul> <p>We recommend that you enable this feature if it is necessary to improve the connections per second. Depending on the load, it might have a limited performance impact on SSL throughput. We recommend that you use this feature during a low-use or maintenance period to minimize a temporary packet loss that can occur during the transition of processing from software to hardware.</p> <p>The following commands were introduced or modified: <b>crypto engine large-mod-accel</b>, <b>clear configure crypto engine</b>, <b>show running-config crypto engine</b>, and <b>show running-config crypto</b>.</p> <p><i>Also available in Version 8.2(3).</i></p>
Microsoft Internet Explorer proxy lockdown control	<p>Enabling this feature hides the Connections tab in Microsoft Internet Explorer for the duration of an AnyConnect VPN session. Disabling the feature leaves the display of the Connections tab unchanged; the default setting for the tab can be shown or hidden, depending on the user registry settings.</p> <p>The following command was introduced: <b>msie-proxy lockdown</b>.</p> <p><i>Also available in Version 8.2(3).</i></p>
Secondary password enhancement	<p>You can now configure SSL VPN support for a common secondary password for all authentications or use the primary password as the secondary password.</p> <p>The following command was modified: <b>secondary-pre-fill-username [use-primary-password   use-common-password] ]</b></p>

**Table 1-2**      ***New Features for ASA Version 8.3(2) (continued)***

Feature	Description
<b>General Features</b>	
No Payload Encryption image for export	<p>For export to some countries, payload encryption cannot be enabled on the Cisco ASA 5500 series. For version 8.3(2), you can now install a No Payload Encryption image (asa832-npe-k8.bin) on the following models:</p> <ul style="list-style-type: none"> <li>• ASA 5505</li> <li>• ASA 5510</li> <li>• ASA 5520</li> <li>• ASA 5540</li> <li>• ASA 5550</li> </ul> <p>Features that are disabled in the No Payload Encryption image include:</p> <ul style="list-style-type: none"> <li>• Unified Communications.</li> <li>• Strong encryption for VPN (DES encryption is still available for VPN).</li> <li>• VPN load balancing (note that the CLI is still present; the feature will not function, however).</li> <li>• Downloading of the dynamic database for the Botnet Traffic Filer (Static black and whitelists are still supported. Note that the CLI is still present; the feature will not function, however.).</li> <li>• Management protocols requiring strong encryption, including SSL, SSHv2, and SNMPv3. You can, however, use SSL or SNMPv3 using base encryption (DES). Also, SSHv1 and SNMPv1 and v2 are still available.</li> </ul> <p>If you attempt to install a Strong Encryption (3DES/AES) license, you see the following warning:</p> <pre>WARNING: Strong encryption types have been disabled in this image; the VPN-3DES-AES license option has been ignored.</pre>

## New Features in Version 8.3(1)

Table 1-3 lists the new features for ASA Version 8.3(1).

**Table 1-3 New Features for ASA Version 8.3(1)**

Feature	Description
<b>Remote Access Features</b>	
Smart Tunnel Enhancements	<p>Logoff enhancement—Smart tunnel can now be logged off when all browser windows have been closed (parent affinity), or you can right click the notification icon in the system tray and confirm log out.</p> <p>Tunnel Policy—An administrator can dictate which connections go through the VPN gateway and which do not. An end user can browse the Internet directly while accessing company internal resources with smart tunnel if the administrator chooses.</p> <p>Simplified configuration of which applications to tunnel—When a smart tunnel is required, a user no longer needs to configure a list of processes that can access smart tunnel and in turn access certain web pages. An “enable smart tunnel” check box for either a bookmark or standalone application allows for an easier configuration process.</p> <p>Group policy home page—Using a check box in ASDM, administrators can now specify their home page in group policy in order to connect via smart tunnel.</p> <p>The following commands were introduced: <b>smart-tunnel network</b>, <b>smart-tunnel tunnel-policy</b>.</p>
Newly Supported Platforms for Browser-based VPN	<p>Release 8.3(1) provides browser-based (clientless) VPN access from the following newly supported platforms:</p> <ul style="list-style-type: none"> <li>Windows 7 x86 (32-bit) and x64 (64-bit) via Internet Explorer 8.x and Firefox 3.x</li> <li>Windows Vista x64 via Internet Explorer 7.x/8.x, or Firefox 3.x.</li> <li>Windows XP x64 via Internet Explorer 6.x/7.x/8.x and Firefox 3.x</li> <li>Mac OS 10.6.x 32- and 64-bit via Safari 4.x and Firefox 3.x.</li> </ul> <p>Firefox 2.x is likely to work, although we no longer test it.</p> <p>Release 8.3(1) introduces browser-based support for 64-bit applications on Mac OS 10.5.</p> <p>Release 8.3(1) now supports smart tunnel access on all 32-bit and 64-bit Windows OSs supported for browser-based VPN access, Mac OS 10.5 running on an Intel processor only, and Mac OS 10.6.x. The adaptive security appliance does not support port forwarding on 64-bit OSs.</p> <p>Browser-based VPN access does not support Web Folders on Windows 7, Vista, and Internet Explorer 8.</p> <p>An ActiveX version of the RDP plug-in is not available for 64-bit browsers.</p> <p><b>Note</b> Windows 2000 and Mac OS X 10.4 are no longer supported for browser-based access.</p>

**Table 1-3**      **New Features for ASA Version 8.3(1) (continued)**

Feature	Description
IPv6 support for IKEv1 LAN-to-LAN VPN connections	<p>For LAN-to-LAN connections using mixed IPv4 and IPv6 addressing, or all IPv6 addressing, the adaptive security appliance supports VPN tunnels if both peers are Cisco ASA 5500 series adaptive security appliances, and if both inside networks have matching addressing schemes (both IPv4 or both IPv6).</p> <p>Specifically, the following topologies are supported when both peers are Cisco ASA 5500 series adaptive security appliances:</p> <ul style="list-style-type: none"> <li>• The adaptive security appliances have IPv4 inside networks and the outside network is IPv6 (IPv4 addresses on the inside interfaces and IPv6 addresses on the outside interfaces).</li> <li>• The adaptive security appliances have IPv6 inside networks and the outside network is IPv4 (IPv6 addresses on the inside interface and IPv4 addresses on the outside interfaces).</li> <li>• The adaptive security appliances have IPv6 inside networks and the outside network is IPv6 (IPv6 addresses on the inside and outside interfaces).</li> </ul> <p> <b>Note</b> The defect CSCtd38078 currently prevents the Cisco ASA 5500 series from connecting to a Cisco IOS device as the peer device of a LAN-to-LAN connection.</p> <p>The following commands were modified or introduced: <b>isakmp enable</b>, <b>crypto map</b>, <b>crypto dynamic-map</b>, <b>tunnel-group</b>, <b>ipv6-vpn-filter</b>, <b>vpn-sessiondb</b>, <b>show crypto isakmp sa</b>, <b>show crypto ipsec sa</b>, <b>show crypto debug-condition</b>, <b>show debug crypto</b>, <b>show vpn-sessiondb</b>, <b>debug crypto condition</b>, <b>debug menu ike</b>.</p>
<b>Firewall Features</b>	
Interface-Independent Access Policies	<p>You can now configure access rules that are applied globally, as well as access rules that are applied to an interface. If the configuration specifies both a global access policy and interface-specific access policies, the interface-specific policies are evaluated before the global policy.</p> <p>The following command was modified: <b>access-group global</b>.</p>
Network and Service Objects	<p>You can now create named network objects that you can use in place of a host, a subnet, or a range of IP addresses in your configuration and named service objects that you can use in place of a protocol and port in your configuration. You can then change the object definition in one place, without having to change any other part of your configuration. This release introduces support for network and service objects in the following features:</p> <ul style="list-style-type: none"> <li>• NAT</li> <li>• Access lists</li> <li>• Network object groups</li> </ul> <p>The following commands were introduced or modified: <b>object network</b>, <b>object service</b>, <b>show running-config object</b>, <b>clear configure object</b>, <b>access-list extended</b>, <b>object-group network</b>.</p>

**Table 1-3**      ***New Features for ASA Version 8.3(1) (continued)***

Feature	Description
Object-group Expansion Rule Reduction	<p>Significantly reduces the network object-group expansion while maintaining a satisfactory level of packet classification performance.</p> <p>The following commands were modified: <b>show object-group</b>, <b>clear object-group</b>, <b>show access-list</b>.</p>
NAT Simplification	<p>The NAT configuration was completely redesigned to allow greater flexibility and ease of use. You can now configure NAT using auto NAT, where you configure NAT as part of the attributes of a network object, and manual NAT, where you can configure more advanced NAT options.</p> <p>The following commands were introduced or modified: <b>nat</b> (in global and object network configuration mode), <b>show nat</b>, <b>show nat pool</b>, <b>show xlate</b>, <b>show running-config nat</b>.</p> <p>The following commands were removed: <b>global</b>, <b>static</b>, <b>nat-control</b>, <b>alias</b>.</p>
Use of Real IP addresses in access lists instead of translated addresses	<p>When using NAT, mapped addresses are no longer required in an access list for many features. You should always use the real, untranslated addresses when configuring these features. Using the real address means that if the NAT configuration changes, you do not need to change the access lists.</p> <p>The following commands and features that use access lists now use real IP addresses. These features are automatically migrated to use real IP addresses when you upgrade to 8.3, unless otherwise noted.</p> <ul style="list-style-type: none"> <li>• <b>access-group</b> command</li> <li>• Modular Policy Framework <b>match access-list</b> command</li> <li>• Botnet Traffic Filter <b>dynamic-filter enable classify-list</b> command</li> <li>• AAA <b>aaa ... match</b> commands</li> <li>• WCCP <b>wccp redirect-list group-list</b> command</li> </ul> <p><b>Note</b> WCCP is not automatically migrated when you upgrade to 8.3.</p>
Threat Detection Enhancements	<p>You can now customize the number of rate intervals for which advanced statistics are collected. The default number of rates was changed from 3 to 1. For basic statistics, advanced statistics, and scanning threat detection, the memory usage was improved.</p> <p>The following commands were modified: <b>threat-detection statistics port number-of-rates</b>, <b>threat-detection statistics protocol number-of-rates</b>, <b>show threat-detection memory</b>.</p>
<b>Unified Communication Features</b>	
SCCP v19 support	The IP phone support in the Cisco Phone Proxy feature was enhanced to include support for version 19 of the SCCP protocol on the list of supported IP phones.

**Table 1-3**      ***New Features for ASA Version 8.3(1) (continued)***

<b>Feature</b>	<b>Description</b>
Cisco Intercompany Media Engine Proxy	<p>Cisco Intercompany Media Engine (UC-IME) enables companies to interconnect on-demand, over the Internet with advanced features made available by VoIP technologies. Cisco Intercompany Media Engine allows for business-to-business federation between Cisco Unified Communications Manager clusters in different enterprises by utilizing peer-to-peer, security, and SIP protocols to create dynamic SIP trunks between businesses. A collection of enterprises work together to end up looking like one large business with inter-cluster trunks between them.</p> <p>The following commands were modified or introduced: <b>uc-ime</b>, <b>fallback hold-down</b>, <b>fallback monitoring</b>, <b>fallback sensitivity-file</b>, <b>mapping-service listening-interface</b>, <b>media-termination</b>, <b>ticket epoch</b>, <b>ucm address</b>, <b>clear configure uc-ime</b>, <b>debug uc-ime</b>, <b>show running-config uc-ime</b>, <b>inspect sip</b>.</p>
SIP Inspection Support for IME	<p>SIP inspection has been enhance to support the new Cisco Intercompany Media Engine (UC-IME) Proxy.</p> <p>The following command was modified: <b>inspect sip</b>.</p>
<b>Monitoring Features</b>	
Time Stamps for Access List Hit Counts	<p>Displays the timestamp, along with the hash value and hit count, for a specified access list.</p> <p>The following command was modified: <b>show access-list</b>.</p>
High Performance Monitoring for ASDM	<p>You can now enable high performance monitoring for ASDM to show the top 200 hosts connected through the adaptive security appliance. Each entry of a host contains the IP address of the host and the number of connections initiated by the host, and is updated every 120 seconds.</p> <p>The following commands were introduced: <b>hpm topn enable</b>, <b>clear configure hpm</b>, <b>show running-config hpm</b>.</p>
<b>Licensing Features</b>	
Non-identical failover licenses	<p>Failover licenses no longer need to be identical on each unit. The license used for both units is the combined license from the primary and secondary units.</p> <p><b>Note</b> For the ASA 5505 and 5510 adaptive security appliances, both units require the Security Plus license; the Base license does not support failover, so you cannot enable failover on a standby unit that only has the Base license.</p> <p>The following commands were modified: <b>show activation-key</b> and <b>show version</b>.</p>

**Table 1-3**      **New Features for ASA Version 8.3(1) (continued)**

Feature	Description
Stackable time-based licenses	Time-based licenses are now stackable. In many cases, you might need to renew your time-based license and have a seamless transition from the old license to the new one. For features that are only available with a time-based license, it is especially important that the license not expire before you can apply the new license. The adaptive security appliance allows you to <i>stack</i> time-based licenses so you do not have to worry about the license expiring or about losing time on your licenses because you installed the new one early. For licenses with numerical tiers, stacking is only supported for licenses with the same capacity, for example, two 1000-session SSL VPN licenses. You can view the state of the licenses using the <code>show activation-key</code> command.
Intercompany Media Engine License	The IME license was introduced.
Multiple time-based licenses active at the same time	You can now install multiple time-based licenses, and have one license per feature active at a time.  The following commands were modified: <b>show activation-key</b> and <b>show version</b> .
Discrete activation and deactivation of time-based licenses.	You can now activate or deactivate time-based licenses using a command.  The following command was modified: <b>activation-key [activate   deactivate]</b> .
<b>General Features</b>	
Master Passphrase	The master passphrase feature allows you to securely store plain text passwords in encrypted format. It provides a master key that is used to universally encrypt or mask all passwords, without changing any functionality.  The following commands were introduced: <b>key config-key password-encryption</b> , <b>password encryption aes</b> .

## Firewall Functional Overview

Firewalls protect inside networks from unauthorized access by users on an outside network. A firewall can also protect inside networks from each other, for example, by keeping a human resources network separate from a user network. If you have network resources that need to be available to an outside user, such as a web or FTP server, you can place these resources on a separate network behind the firewall, called a *demilitarized zone* (DMZ). The firewall allows limited access to the DMZ, but because the DMZ only includes the public servers, an attack there only affects the servers and does not affect the other inside networks. You can also control when inside users access outside networks (for example, access to the Internet), by allowing only certain addresses out, by requiring authentication or authorization, or by coordinating with an external URL filtering server.

When discussing networks connected to a firewall, the *outside* network is in front of the firewall, the *inside* network is protected and behind the firewall, and a *DMZ*, while behind the firewall, allows limited access to outside users. Because the adaptive security appliance lets you configure many interfaces with varied security policies, including many inside interfaces, many DMZs, and even many outside interfaces if desired, these terms are used in a general sense only.

This section includes the following topics:

- [Security Policy Overview, page 1-11](#)
- [Firewall Mode Overview, page 1-14](#)
- [Stateful Inspection Overview, page 1-14](#)

## Security Policy Overview

A security policy determines which traffic is allowed to pass through the firewall to access another network. By default, the adaptive security appliance allows traffic to flow freely from an inside network (higher security level) to an outside network (lower security level). You can apply actions to traffic to customize the security policy. This section includes the following topics:

- [Permitting or Denying Traffic with Access Lists, page 1-11](#)
- [Applying NAT, page 1-11](#)
- [Protecting from IP Fragments, page 1-12](#)
- [Using AAA for Through Traffic, page 1-12](#)
- [Applying HTTP, HTTPS, or FTP Filtering, page 1-12](#)
- [Applying Application Inspection, page 1-12](#)
- [Sending Traffic to the Advanced Inspection and Prevention Security Services Module, page 1-12](#)
- [Sending Traffic to the Content Security and Control Security Services Module, page 1-12](#)
- [Applying QoS Policies, page 1-13](#)
- [Applying Connection Limits and TCP Normalization, page 1-13](#)
- [Enabling Threat Detection, page 1-13](#)
- [Enabling the Botnet Traffic Filter, page 1-13](#)
- [Configuring Cisco Unified Communications, page 1-13](#)

### Permitting or Denying Traffic with Access Lists

You can apply an access list to limit traffic from inside to outside, or allow traffic from outside to inside. For transparent firewall mode, you can also apply an EtherType access list to allow non-IP traffic.

### Applying NAT

Some of the benefits of NAT include the following:

- You can use private addresses on your inside networks. Private addresses are not routable on the Internet.
- NAT hides the local addresses from other networks, so attackers cannot learn the real address of a host.

- NAT can resolve IP routing problems by supporting overlapping IP addresses.

## Protecting from IP Fragments

The adaptive security appliance provides IP fragment protection. This feature performs full reassembly of all ICMP error messages and virtual reassembly of the remaining IP fragments that are routed through the adaptive security appliance. Fragments that fail the security check are dropped and logged. Virtual reassembly cannot be disabled.

## Using AAA for Through Traffic

You can require authentication and/or authorization for certain types of traffic, for example, for HTTP. The adaptive security appliance also sends accounting information to a RADIUS or TACACS+ server.

## Applying HTTP, HTTPS, or FTP Filtering

Although you can use access lists to prevent outbound access to specific websites or FTP servers, configuring and managing web usage this way is not practical because of the size and dynamic nature of the Internet. We recommend that you use the adaptive security appliance in conjunction with a separate server running one of the following Internet filtering products:

- Websense Enterprise
- Secure Computing SmartFilter

## Applying Application Inspection

Inspection engines are required for services that embed IP addressing information in the user data packet or that open secondary channels on dynamically assigned ports. These protocols require the adaptive security appliance to do a deep packet inspection.

## Sending Traffic to the Advanced Inspection and Prevention Security Services Module

If your model supports the AIP SSM for intrusion prevention, then you can send traffic to the AIP SSM for inspection. The AIP SSM is an intrusion prevention services module that monitors and performs real-time analysis of network traffic by looking for anomalies and misuse based on an extensive, embedded signature library. When the system detects unauthorized activity, it can terminate the specific connection, permanently block the attacking host, log the incident, and send an alert to the device manager. Other legitimate connections continue to operate independently without interruption. For more information, see *Configuring the Cisco Intrusion Prevention System Sensor Using the Command Line Interface*.

## Sending Traffic to the Content Security and Control Security Services Module

If your model supports it, the CSC SSM provides protection against viruses, spyware, spam, and other unwanted traffic. It accomplishes this by scanning the FTP, HTTP, POP3, and SMTP traffic that you configure the adaptive adaptive security appliance to send to it.

## Applying QoS Policies

Some network traffic, such as voice and streaming video, cannot tolerate long latency times. QoS is a network feature that lets you give priority to these types of traffic. QoS refers to the capability of a network to provide better service to selected network traffic.

## Applying Connection Limits and TCP Normalization

You can limit TCP and UDP connections and embryonic connections. Limiting the number of connections and embryonic connections protects you from a DoS attack. The adaptive security appliance uses the embryonic limit to trigger TCP Intercept, which protects inside systems from a DoS attack perpetrated by flooding an interface with TCP SYN packets. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination.

TCP normalization is a feature consisting of advanced TCP connection settings designed to drop packets that do not appear normal.

## Enabling Threat Detection

You can configure scanning threat detection and basic threat detection, and also how to use statistics to analyze threats.

Basic threat detection detects activity that might be related to an attack, such as a DoS attack, and automatically sends a system log message.

A typical scanning attack consists of a host that tests the accessibility of every IP address in a subnet (by scanning through many hosts in the subnet or sweeping through many ports in a host or subnet). The scanning threat detection feature determines when a host is performing a scan. Unlike IPS scan detection that is based on traffic signatures, the adaptive security appliance scanning threat detection feature maintains an extensive database that contains host statistics that can be analyzed for scanning activity.

The host database tracks suspicious activity such as connections with no return activity, access of closed service ports, vulnerable TCP behaviors such as non-random IPID, and many more behaviors.

You can configure the adaptive security appliance to send system log messages about an attacker or you can automatically shun the host.

## Enabling the Botnet Traffic Filter

Malware is malicious software that is installed on an unknowing host. Malware that attempts network activity such as sending private data (passwords, credit card numbers, key strokes, or proprietary data) can be detected by the Botnet Traffic Filter when the malware starts a connection to a known bad IP address. The Botnet Traffic Filter checks incoming and outgoing connections against a dynamic database of known bad domain names and IP addresses (the blacklist), and then logs any suspicious activity. When you see syslog messages about the malware activity, you can take steps to isolate and disinfect the host.

## Configuring Cisco Unified Communications

The Cisco ASA 5500 Series appliances are a strategic platform to provide proxy functions for unified communications deployments. The purpose of a proxy is to terminate and reoriginate connections between a client and server. The proxy delivers a range of security functions such as traffic inspection, protocol conformance, and policy control to ensure security for the internal network. An increasingly popular function of a proxy is to terminate encrypted connections in order to apply security policies while maintaining confidentiality of connections.

## Firewall Mode Overview

The adaptive security appliance runs in two different firewall modes:

- Routed
- Transparent

In routed mode, the adaptive security appliance is considered to be a router hop in the network.

In transparent mode, the adaptive security appliance acts like a “bump in the wire,” or a “stealth firewall,” and is not considered a router hop. The adaptive security appliance connects to the same network on its inside and outside interfaces.

You might use a transparent firewall to simplify your network configuration. Transparent mode is also useful if you want the firewall to be invisible to attackers. You can also use a transparent firewall for traffic that would otherwise be blocked in routed mode. For example, a transparent firewall can allow multicast streams using an EtherType access list.

## Stateful Inspection Overview

All traffic that goes through the adaptive security appliance is inspected using the Adaptive Security Algorithm and either allowed through or dropped. A simple packet filter can check for the correct source address, destination address, and ports, but it does not check that the packet sequence or flags are correct. A filter also checks every packet against the filter, which can be a slow process.

**Note**

The TCP state bypass feature allows you to customize the packet flow. See the [“TCP State Bypass” section on page 49-3](#).

A stateful firewall like the adaptive security appliance, however, takes into consideration the state of a packet:

- Is this a new connection?

If it is a new connection, the adaptive security appliance has to check the packet against access lists and perform other tasks to determine if the packet is allowed or denied. To perform this check, the first packet of the session goes through the “session management path,” and depending on the type of traffic, it might also pass through the “control plane path.”

The session management path is responsible for the following tasks:

- Performing the access list checks
- Performing route lookups
- Allocating NAT translations (xlates)
- Establishing sessions in the “fast path”

Some packets that require Layer 7 inspection (the packet payload must be inspected or altered) are passed on to the control plane path. Layer 7 inspection engines are required for protocols that have two or more channels: a data channel, which uses well-known port numbers, and a control channel, which uses different port numbers for each session. These protocols include FTP, H.323, and SNMP.

- Is this an established connection?

If the connection is already established, the adaptive security appliance does not need to re-check packets; most matching packets can go through the “fast” path in both directions. The fast path is responsible for the following tasks:

- IP checksum verification
- Session lookup
- TCP sequence number check
- NAT translations based on existing sessions
- Layer 3 and Layer 4 header adjustments

For UDP or other connectionless protocols, the adaptive security appliance creates connection state information so that it can also use the fast path.

Data packets for protocols that require Layer 7 inspection can also go through the fast path.

Some established session packets must continue to go through the session management path or the control plane path. Packets that go through the session management path include HTTP packets that require inspection or content filtering. Packets that go through the control plane path include the control packets for protocols that require Layer 7 inspection.

## VPN Functional Overview

A VPN is a secure connection across a TCP/IP network (such as the Internet) that appears as a private connection. This secure connection is called a tunnel. The adaptive security appliance uses tunneling protocols to negotiate security parameters, create and manage tunnels, encapsulate packets, transmit or receive them through the tunnel, and unencapsulate them. The adaptive security appliance functions as a bidirectional tunnel endpoint: it can receive plain packets, encapsulate them, and send them to the other end of the tunnel where they are unencapsulated and sent to their final destination. It can also receive encapsulated packets, unencapsulate them, and send them to their final destination. The adaptive security appliance invokes various standard protocols to accomplish these functions.

The adaptive security appliance performs the following functions:

- Establishes tunnels
- Negotiates tunnel parameters
- Authenticates users
- Assigns user addresses
- Encrypts and decrypts data
- Manages security keys
- Manages data transfer across the tunnel
- Manages data transfer inbound and outbound as a tunnel endpoint or router

The adaptive security appliance invokes various standard protocols to accomplish these functions.

## Security Context Overview

You can partition a single adaptive security appliance into multiple virtual devices, known as security contexts. Each context is an independent device, with its own security policy, interfaces, and administrators. Multiple contexts are similar to having multiple standalone devices. Many features are supported in multiple context mode, including routing tables, firewall features, IPS, and management. Some features are not supported, including VPN and dynamic routing protocols.

In multiple context mode, the adaptive security appliance includes a configuration for each context that identifies the security policy, interfaces, and almost all the options you can configure on a standalone device. The system administrator adds and manages contexts by configuring them in the system configuration, which, like a single mode configuration, is the startup configuration. The system configuration identifies basic settings for the adaptive security appliance. The system configuration does not include any network interfaces or network settings for itself; rather, when the system needs to access network resources (such as downloading the contexts from the server), it uses one of the contexts that is designated as the admin context.

The admin context is just like any other context, except that when a user logs into the admin context, then that user has system administrator rights and can access the system and all other contexts.

**Note**

You can run all your contexts in routed mode or transparent mode; you cannot run some contexts in one mode and others in another.

Multiple context mode supports static routing only.

# CHAPTER 2

## Getting Started

---

This chapter describes how to get started with your adaptive security appliance. This chapter includes the following sections:

- [Factory Default Configurations, page 2-1](#)
- [Accessing the Command-Line Interface, page 2-4](#)
- [Working with the Configuration, page 2-5](#)
- [Applying Configuration Changes to Connections, page 2-10](#)

## Factory Default Configurations

The factory default configuration is the configuration applied by Cisco to new adaptive security appliances.

For the ASA 5510 and higher adaptive security appliances, the factory default configuration configures an interface for management so you can connect to it using ASDM, with which you can then complete your configuration.

For the ASA 5505 adaptive security appliance, the factory default configuration configures interfaces and NAT so that the adaptive security appliance is ready to use in your network immediately.

The factory default configuration is available only for routed firewall mode and single context mode. See [Chapter 5, “Configuring Multiple Context Mode,”](#) for more information about multiple context mode. See [Chapter 4, “Configuring the Transparent or Routed Firewall,”](#) for more information about routed and transparent firewall mode.

### Note

In addition to the image files and the (hidden) default configuration, the following folders and files are standard in flash memory: log/, crypto\_archive/, and coredumpinfo/coredump.cfg. The date on these files may not match the date of the image files in flash memory. These files aid in potential troubleshooting; they do not indicate that a failure has occurred.

This section includes the following topics:

- [Restoring the Factory Default Configuration, page 2-2](#)
- [ASA 5505 Default Configuration, page 2-2](#)
- [ASA 5510 and Higher Default Configuration, page 2-4](#)

## Restoring the Factory Default Configuration

This section describes how to restore the factory default configuration.

### Limitations

This feature is available only in routed firewall mode; transparent mode does not support IP addresses for interfaces. In addition, this feature is available only in single context mode; an adaptive security appliance with a cleared configuration does not have any defined contexts to configure automatically using this feature.

### Detailed Steps

	Command	Purpose
Step 1	<pre><b>configure factory-default</b> [<i>ip_address</i> [<i>mask</i>]]</pre> <p><b>Example:</b></p> <pre>hostname(config)# <b>configure</b> <b>factory-default</b> 10.1.1.1 255.255.255.0</pre>	<p>Restores the factory default configuration.</p> <p>If you specify the <i>ip_address</i>, then you set the inside or management interface IP address, depending on your model, instead of using the default IP address of 192.168.1.1. The <b>http</b> command uses the subnet you specify. Similarly, the <b>dhcpd address</b> command range consists of addresses within the subnet that you specify.</p> <p><b>Note</b> This command also clears the <b>boot system</b> command, if present, along with the rest of the configuration. The <b>boot system</b> command lets you boot from a specific image, including an image on the external flash memory card. The next time you reload the adaptive security appliance after restoring the factory configuration, it boots from the first image in internal flash memory; if you do not have an image in internal flash memory, the adaptive security appliance does not boot.</p>
Step 2	<pre><b>write memory</b></pre> <p><b>Example:</b></p> <pre>active(config)# write memory</pre>	<p>Saves the default configuration to flash memory. This command saves the running configuration to the default location for the startup configuration, even if you previously configured the <b>boot config</b> command to set a different location; when the configuration was cleared, this path was also cleared.</p>

### What to Do Next

To configure additional settings that are useful for a full configuration, see the **setup** command.

## ASA 5505 Default Configuration

The default factory configuration for the ASA 5505 adaptive security appliance configures the following:

- An inside VLAN 1 interface that includes the Ethernet 0/1 through 0/7 switch ports. If you did not set the IP address in the **configure factory-default** command, then the VLAN 1 IP address and mask are 192.168.1.1 and 255.255.255.0.

- An outside VLAN 2 interface that includes the Ethernet 0/0 switch port. VLAN 2 derives its IP address using DHCP.
- The default route is also derived from DHCP.
- All inside IP addresses are translated when accessing the outside using interface PAT.
- By default, inside users can access the outside, and outside users are prevented from accessing the inside.
- The DHCP server is enabled on the adaptive security appliance, so a PC connecting to the VLAN 1 interface receives an address between 192.168.1.2 and 192.168.1.254.
- The HTTP server is enabled for ASDM and is accessible to users on the 192.168.1.0 network.

The configuration consists of the following commands:

```
interface Ethernet 0/0
  switchport access vlan 2
  no shutdown
interface Ethernet 0/1
  switchport access vlan 1
  no shutdown
interface Ethernet 0/2
  switchport access vlan 1
  no shutdown
interface Ethernet 0/3
  switchport access vlan 1
  no shutdown
interface Ethernet 0/4
  switchport access vlan 1
  no shutdown
interface Ethernet 0/5
  switchport access vlan 1
  no shutdown
interface Ethernet 0/6
  switchport access vlan 1
  no shutdown
interface Ethernet 0/7
  switchport access vlan 1
  no shutdown
interface vlan2
  nameif outside
  no shutdown
  ip address dhcp setroute
interface vlan1
  nameif inside
  ip address 192.168.1.1 255.255.255.0
  security-level 100
  no shutdown
object network obj_any
  subnet 0 0
  nat (inside,outside) dynamic interface
http server enable
http 192.168.1.0 255.255.255.0 inside
dhcpd address 192.168.1.2-192.168.1.254 inside
dhcpd auto_config outside
dhcpd enable inside
logging asdm informational
```

## ASA 5510 and Higher Default Configuration

The default factory configuration for the ASA 5510 and higher adaptive security appliance configures the following:

- The management interface, Management 0/0. If you did not set the IP address in the **configure factory-default** command, then the IP address and mask are 192.168.1.1 and 255.255.255.0.
- The DHCP server is enabled on the adaptive security appliance, so a PC connecting to the interface receives an address between 192.168.1.2 and 192.168.1.254.
- The HTTP server is enabled for ASDM and is accessible to users on the 192.168.1.0 network.

The configuration consists of the following commands:

```
interface management 0/0
  ip address 192.168.1.1 255.255.255.0
  nameif management
  security-level 100
  no shutdown
asdm logging informational 100
asdm history enable
http server enable
http 192.168.1.0 255.255.255.0 management
dhcpd address 192.168.1.2-192.168.1.254 management
dhcpd lease 3600
dhcpd ping_timeout 750
dhcpd enable management
```

## Accessing the Command-Line Interface

For initial configuration, access the command-line interface directly from the console port. Later, you can configure remote access using Telnet or SSH according to [Chapter 34, “Configuring Management Access.”](#) If your system is already in multiple context mode, then accessing the console port places you in the system execution space. See [Chapter 5, “Configuring Multiple Context Mode,”](#) for more information about multiple context mode.

### Note

If you want to use ASDM to configure the adaptive security appliance instead of the command-line interface, you can connect to the default management address of 192.168.1.1 (if your adaptive security appliance includes a factory default configuration. See the [“Factory Default Configurations”](#) section on [page 2-1.](#)). On the ASA 5510 and higher adaptive security appliances, the interface to which you connect with ASDM is Management 0/0. For the ASA 5505 adaptive security appliance, the switch port to which you connect with ASDM is any port, except for Ethernet 0/0. If you do not have a factory default configuration, follow the steps in this section to access the command-line interface. You can then configure the minimum parameters to access ASDM by entering the **setup** command.

To access the command-line interface, perform the following steps:

- Step 1** Connect a PC to the console port using the provided console cable, and connect to the console using a terminal emulator set for 9600 baud, 8 data bits, no parity, 1 stop bit, no flow control.  
  
See the hardware guide that came with your adaptive security appliance for more information about the console cable.
- Step 2** Press the **Enter** key to see the following prompt:

```
hostname>
```

This prompt indicates that you are in user EXEC mode.

**Step 3** To access privileged EXEC mode, enter the following command:

```
hostname> enable
```

The following prompt appears:

```
Password:
```

**Step 4** Enter the enable password at the prompt.

By default, the password is blank, and you can press the **Enter** key to continue. See the [“Changing the Enable Password” section on page 7-2](#) to change the enable password.

The prompt changes to:

```
hostname#
```

To exit privileged mode, enter the **disable**, **exit**, or **quit** command.

**Step 5** To access global configuration mode, enter the following command:

```
hostname# configure terminal
```

The prompt changes to the following:

```
hostname(config)#
```

To exit global configuration mode, enter the **exit**, **quit**, or **end** command.

---

## Working with the Configuration

This section describes how to work with the configuration. The adaptive security appliance loads the configuration from a text file, called the startup configuration. This file resides by default as a hidden file in internal flash memory. You can, however, specify a different path for the startup configuration. (For more information, see [Chapter 76, “Managing Software and Configurations.”](#))

When you enter a command, the change is made only to the running configuration in memory. You must manually save the running configuration to the startup configuration for your changes to remain after a reboot.

The information in this section applies to both single and multiple security contexts, except where noted. Additional information about contexts is in [Chapter 5, “Configuring Multiple Context Mode.”](#)

This section includes the following topics:

- [Saving Configuration Changes, page 2-6](#)
- [Copying the Startup Configuration to the Running Configuration, page 2-8](#)
- [Viewing the Configuration, page 2-8](#)
- [Clearing and Removing Configuration Settings, page 2-9](#)
- [Creating Text Configuration Files Offline, page 2-9](#)

## Saving Configuration Changes

This section describes how to save your configuration and includes the following topics:

- [Saving Configuration Changes in Single Context Mode, page 2-6](#)
- [Saving Configuration Changes in Multiple Context Mode, page 2-6](#)

### Saving Configuration Changes in Single Context Mode

To save the running configuration to the startup configuration, enter the following command:

Command	Purpose
<code>write memory</code>	Saves the running configuration to the startup configuration.
<b>Example:</b> <code>hostname# write memory</code>	<b>Note</b> The <b>copy running-config startup-config</b> command is equivalent to the <b>write memory</b> command.

### Saving Configuration Changes in Multiple Context Mode

You can save each context (and system) configuration separately, or you can save all context configurations at the same time. This section includes the following topics:

- [Saving Each Context and System Separately, page 2-6](#)
- [Saving All Context Configurations at the Same Time, page 2-7](#)

#### Saving Each Context and System Separately

To save the system or context configuration, enter the following command within the system or context:

Command	Purpose
<code>write memory</code>	Saves the running configuration to the startup configuration.
<b>Example:</b> <code>hostname# write memory</code>	For multiple context mode, context startup configurations can reside on external servers. In this case, the adaptive security appliance saves the configuration back to the server you identified in the context URL, except for an HTTP or HTTPS URL, which do not let you save the configuration to the server.
	<b>Note</b> The <b>copy running-config startup-config</b> command is equivalent to the <b>write memory</b> command.

## Saving All Context Configurations at the Same Time

To save all context configurations at the same time, as well as the system configuration, enter the following command in the system execution space:

Command	Purpose
<b>write memory all</b> [/noconfirm]  <b>Example:</b> hostname# write memory all /noconfirm	<p>Saves the running configuration to the startup configuration for all contexts and the system configuration.</p> <p>If you do not enter the <b>/noconfirm</b> keyword, you see the following prompt: Are you sure [Y/N]:</p> <p>After you enter <b>Y</b>, the adaptive security appliance saves the system configuration and each context. Context startup configurations can reside on external servers. In this case, the adaptive security appliance saves the configuration back to the server you identified in the context URL, except for an HTTP or HTTPS URL, which do not let you save the configuration to the server.</p>

After the adaptive security appliance saves each context, the following message appears:

```
'Saving context 'b' ... ( 1/3 contexts saved ) '
```

Sometimes, a context is not saved because of an error. See the following information for errors:

- For contexts that are not saved because of low memory, the following message appears:  
The context 'context a' could not be saved due to Unavailability of resources
- For contexts that are not saved because the remote destination is unreachable, the following message appears:

```
The context 'context a' could not be saved due to non-reachability of destination
```

- For contexts that are not saved because the context is locked, the following message appears:  
Unable to save the configuration for the following contexts as these contexts are locked.  
context 'a' , context 'x' , context 'z' .

A context is only locked if another user is already saving the configuration or in the process of deleting the context.

- For contexts that are not saved because the startup configuration is read-only (for example, on an HTTP server), the following message report is printed at the end of all other messages:

```
Unable to save the configuration for the following contexts as these contexts have read-only config-urls:  
context 'a' , context 'b' , context 'c' .
```

- For contexts that are not saved because of bad sectors in the flash memory, the following message appears:

```
The context 'context a' could not be saved due to Unknown errors
```

## Copying the Startup Configuration to the Running Configuration

Copy a new startup configuration to the running configuration using one of the following options.

Command	Purpose
<code>copy startup-config running-config</code>	Merges the startup configuration with the running configuration. A merge adds any new commands from the new configuration to the running configuration. If the configurations are the same, no changes occur. If commands conflict or if commands affect the running of the context, then the effect of the merge depends on the command. You might get errors, or you might have unexpected results.
<code>reload</code>	Reloads the adaptive security appliance, which loads the startup configuration and discards the running configuration.
<code>clear configure all</code> <code>copy startup-config running-config</code>	Loads the startup configuration and discards the running configuration without requiring a reload.

## Viewing the Configuration

The following commands let you view the running and startup configurations.

Command	Purpose
<code>show running-config</code>	Views the running configuration.
<code>show running-config <i>command</i></code>	Views the running configuration of a specific command.
<code>show startup-config</code>	Views the startup configuration.

## Clearing and Removing Configuration Settings

To erase settings, enter one of the following commands.

Command	Purpose
<code>clear configure configurationcommand</code> [ <i>level2configurationcommand</i> ]	<p>Clears all the configuration for a specified command. If you only want to clear the configuration for a specific version of the command, you can enter a value for <i>level2configurationcommand</i>.</p> <p>For example, to clear the configuration for all <b>aaa</b> commands, enter the following command:</p> <pre>hostname(config)# clear configure aaa</pre> <p>To clear the configuration for only <b>aaa authentication</b> commands, enter the following command:</p> <pre>hostname(config)# clear configure aaa authentication</pre>
<code>no configurationcommand</code> [ <i>level2configurationcommand</i> ] <i>qualifier</i>	<p>Disables the specific parameters or options of a command. In this case, you use the <b>no</b> command to remove the specific configuration identified by <i>qualifier</i>.</p> <p>For example, to remove a specific <b>nat</b> command, enter enough of the command to identify it uniquely as follows:</p> <pre>hostname(config)# no nat (inside) 1</pre>
<code>write erase</code>	Erases the startup configuration.
<code>clear configure all</code>	<p>Erases the running configuration.</p> <p><b>Note</b> In multiple context mode, if you enter <b>clear configure all</b> from the system configuration, you also remove all contexts and stop them from running. The context configuration files are not erased, and remain in their original location.</p>

## Creating Text Configuration Files Offline

This guide describes how to use the CLI to configure the adaptive security appliance; when you save commands, the changes are written to a text file. Instead of using the CLI, however, you can edit a text file directly on your PC and paste a configuration at the configuration mode command-line prompt in its entirety, or line by line. Alternatively, you can download a text file to the adaptive security appliance internal flash memory. See [Chapter 76, “Managing Software and Configurations,”](#) for information on downloading the configuration file to the adaptive security appliance.

In most cases, commands described in this guide are preceded by a CLI prompt. The prompt in the following example is “hostname(config)#”:

```
hostname(config)# context a
```

In the text configuration file you are not prompted to enter commands, so the prompt is omitted as follows:

```
context a
```

For additional information about formatting the file, see [Appendix A, “Using the Command-Line Interface.”](#)

# Applying Configuration Changes to Connections

When you make security policy changes to the configuration, all *new* connections use the new security policy. Existing connections continue to use the policy that was configured at the time of the connection establishment. To ensure that all connections use the new policy, you need to disconnect the current connections so they can reconnect using the new policy. To disconnect connections, enter one of the following commands:

Command	Purpose
<code>clear local-host [ip_address] [all]</code>	<p>This command reinitializes per-client run-time states such as connection limits and embryonic limits. As a result, this command removes any connection that uses those limits. See the <b>show local-host all</b> command to view all current connections per host.</p> <p>With no arguments, this command clears all affected through-the-box connections. To also clear to-the-box connections (including your current management session), use the <b>all</b> keyword. To clear connections to and from a particular IP address, use the <i>ip_address</i> argument.</p>
<code>clear conn [all] [protocol {tcp   udp}] [address src_ip[-src_ip] [netmask mask]] [port src_port[-src_port]] [address dest_ip[-dest_ip] [netmask mask]] [port dest_port[-dest_port]]</code>	<p>This command terminates connections in any state. See the <b>show conn</b> command to view all current connections.</p> <p>With no arguments, this command clears all through-the-box connections. To also clear to-the-box connections (including your current management session), use the <b>all</b> keyword. To clear specific connections based on the source IP address, destination IP address, port, and/or protocol, you can specify the desired options.</p>
<code>clear xlate [arguments]</code>	<p>This command clears dynamic NAT sessions; static sessions are not affected. As a result, it removes any connections using those NAT sessions.</p> <p>With no arguments, this command clears all NAT sessions. See the <i>Cisco ASA 5500 Series Command Reference</i> for more information about the arguments available.</p>

## CHAPTER 3

# Managing Feature Licenses

---

A license specifies the options that are enabled on a given adaptive security appliance. This document describes how to obtain a license activation key and how to activate it. It also describes the available licenses for each model.

**Note**

This chapter describes licensing for Version 8.3; for other versions, see the licensing documentation that applies to your version:

[http://www.cisco.com/en/US/products/ps6120/products\\_licensing\\_information\\_listing.html](http://www.cisco.com/en/US/products/ps6120/products_licensing_information_listing.html)

---

This chapter includes the following sections:

- [Supported Feature Licenses Per Model, page 3-1](#)
- [Information About Feature Licenses, page 3-12](#)
- [Guidelines and Limitations, page 3-22](#)
- [Viewing Your Current License, page 3-24](#)
- [Obtaining an Activation Key, page 3-29](#)
- [Activating or Deactivating Keys, page 3-30](#)
- [Configuring a Shared License, page 3-31](#)
- [Feature History for Licensing, page 3-36](#)

## Supported Feature Licenses Per Model

This section describes the licenses available for each model as well as important notes about licenses. This section includes the following topics:

- [Licenses Per Model, page 3-2](#)
- [License Notes, page 3-9](#)
- [VPN License and Feature Compatibility, page 3-12](#)

## Licenses Per Model

This section lists the feature licenses available for each model:

- ASA 5505, [Table 3-1 on page 3-3](#)
- ASA 5510, [Table 3-2 on page 3-4](#)
- ASA 5520, [Table 3-3 on page 3-5](#)
- ASA 5540, [Table 3-4 on page 3-6](#)
- ASA 5550, [Table 3-5 on page 3-7](#)
- ASA 5580, [Table 3-6 on page 3-8](#)

Items that are in *italics* are separate, optional licenses with which that you can replace the Base or Security Plus license. You can mix and match licenses, for example, the 10 security context license plus the Strong Encryption license; or the 500 Clientless SSL VPN license plus the GTP/GPRS license; or all four licenses together.

Table 3-1 shows the licenses for the ASA 5505.

**Table 3-1 ASA 5505 Adaptive Security Appliance License Features**

ASA 5505	Base License				Security Plus		
Firewall Licenses							
Botnet Traffic Filter <sup>1</sup>	Disabled		Optional Time-based license: Available		Disabled		Optional Time-based license: Available
Firewall Conns, Concurrent	10 K				25 K		
GTP/GPRS	No support				No support		
Intercompany Media Engine <sup>1</sup>	Disabled		Optional license: Available		Disabled		Optional license: Available
Unified Comm. Sessions <sup>1</sup>	2	Optional license: 24			2	Optional license: 24	
VPN Licenses <sup>2</sup>							
Adv. Endpoint Assessment	Disabled		Optional license: Available		Disabled		Optional license: Available
AnyConnect Essentials <sup>1</sup>	Disabled		Optional license: Available		Disabled		Optional license: Available
AnyConnect Mobile <sup>1</sup>	Disabled		Optional license: Available		Disabled		Optional license: Available
AnyConnect Premium SSL VPN Edition (sessions) <sup>1</sup>	2	Optional Permanent or Time-based licenses:			2	Optional Permanent or Time-based licenses:	
		10	25	10		25	
IPSec VPN (sessions) <sup>1</sup>	10 (max. 25 combined IPSec and SSL VPN)				25 (max. 25 combined IPSec and SSL VPN)		
VPN Load Balancing <sup>1</sup>	No support				No support		
General Licenses							
Encryption	Base (DES)		Opt. lic.: Strong (3DES/AES)		Base (DES)		Opt. lic.: Strong (3DES/AES)
Failover	No support				Active/Standby (no stateful failover)		
Security Contexts	No support				No support		
Users, concurrent <sup>3</sup>	10 <sup>4</sup>	Optional licenses:		10 <sup>4</sup>	Optional licenses:		
		50	Unlimited		50	Unlimited	
VLANs/Zones, Maximum	3 (2 regular zones and 1 restricted zone)				20		
VLAN Trunk, Maximum	No support				8 trunks		

1. See the “License Notes” section on page 3-9.

2. See the “VPN License and Feature Compatibility” section on page 3-12.

3. In routed mode, hosts on the inside (Business and Home VLANs) count towards the limit when they communicate with the outside (Internet VLAN), including when the inside initiates a connection to the outside as well as when the outside initiates a connection to the inside. Note that even when the outside initiates a connection to the inside, outside hosts are *not* counted towards the limit; only the inside hosts count. Hosts that initiate traffic between Business and Home are also not counted towards the limit. The interface associated with the default route is considered to be the outside Internet interface. If there is no default route, hosts on all interfaces are counted toward the limit. In transparent mode, the interface with the lowest number of hosts is counted towards the host limit. See the **show local-host** command to view host limits.

4. For a 10-user license, the max. DHCP clients is 32. For 50 users, the max. is 128. For unlimited users, the max. is 250, which is the max. for other models.

Table 3-2 shows the licenses for the ASA 5510.

**Table 3-2 ASA 5510 Adaptive Security Appliance License Features**

ASA 5510	Base License					Security Plus						
Firewall Licenses												
Botnet Traffic Filter <sup>1</sup>	Disabled		Optional Time-based license: Available			Disabled		Optional Time-based license: Available				
Firewall Conns, Concurrent	50 K					130 K						
GTP/GPRS	No support					No support						
Intercompany Media Engine <sup>1</sup>	Disabled		Optional license: Available			Disabled		Optional license: Available				
Unified Comm. Sessions <sup>1</sup>	2	Optional licenses:				2	Optional licenses:					
		24	50	100	24		50	100				
VPN Licenses <sup>2</sup>												
Adv. Endpoint Assessment	Disabled		Optional license: Available			Disabled		Optional license: Available				
AnyConnect Essentials <sup>1</sup>	Disabled		Optional license: Available			Disabled		Optional license: Available				
AnyConnect Mobile <sup>1</sup>	Disabled		Optional license: Available			Disabled		Optional license: Available				
AnyConnect Premium SSL VPN Edition (sessions)	2	Optional Permanent or Time-based licenses:					2	Optional Permanent or Time-based licenses:				
		10	25	50	100	250		10	25	50	100	250
	Optional Shared licenses: Participant or Server. For the Server, these licenses are available: <sup>1</sup>					Optional Shared licenses: Participant or Server. For the Server, these licenses are available: <sup>1</sup>						
	500-50,000 in increments of 500		50,000-545,000 in increments of 1000			500-50,000 in increments of 500		50,000-545,000 in increments of 1000				
IPSec VPN (sessions) <sup>1</sup>	250 (max. 250 combined IPSec and SSL VPN)					250 (max. 250 combined IPSec and SSL VPN)						
VPN Load Balancing <sup>1</sup>	No support					Supported						
General Licenses												
Encryption	Base (DES)		Opt. lic.: Strong (3DES/AES)			Base (DES)		Opt. lic.: Strong (3DES/AES)				
Failover	No support					Active/Standby or Active/Active <sup>1</sup>						
Interface Speed	All: Fast Ethernet					Ethernet 0/0 and 0/1: Gigabit Ethernet <sup>3</sup> Ethernet 0/2, 0/3, and 0/4 (and any others): Fast Ethernet						
Security Contexts	No support					2	Optional licenses:					
							5					
VLANs, Maximum	50					100						

1. See the “License Notes” section on page 3-9.

2. See the “VPN License and Feature Compatibility” section on page 3-12.

3. Although the Ethernet 0/0 and 0/1 ports are Gigabit Ethernet, they are still identified as “Ethernet” in the software.

Table 3-3 shows the licenses for the ASA 5520.

**Table 3-3 ASA 5520 Adaptive Security Appliance License Features**

ASA 5520	Base License							
Firewall Licenses								
Botnet Traffic Filter <sup>1</sup>	Disabled		Optional Time-based license: Available					
Firewall Conns, Concurrent	280 K							
GTP/GPRS	Disabled		Optional license: Available					
Intercompany Media Engine <sup>1</sup>	Disabled		Optional license: Available					
Unified Communications Proxy Sessions <sup>1</sup>	2	Optional licenses:						
		24	50	100	250	500	750	1000
VPN Licenses <sup>2</sup>								
Adv. Endpoint Assessment	Disabled		Optional license: Available					
AnyConnect Essentials <sup>1</sup>	Disabled		Optional license: Available					
AnyConnect Mobile <sup>1</sup>	Disabled		Optional license: Available					
AnyConnect Premium SSL VPN Edition (sessions)	2	Optional Permanent or Time-based licenses:						
		10	25	50	100	250	500	750
	Optional Shared licenses: Participant or Server. For the Server, these licenses are available: <sup>1</sup>							
	500-50,000 in increments of 500					50,000-545,000 in increments of 1000		
IPSec VPN (sessions) <sup>1</sup>	750 (max. 750 combined IPSec and SSL VPN)							
VPN Load Balancing <sup>1</sup>	Supported							
General Licenses								
Encryption	Base (DES)		Optional license: Strong (3DES/AES)					
Failover	Active/Standby or Active/Active <sup>1</sup>							
Security Contexts	2	Optional licenses:						
		5	10	20				
VLANs, Maximum	150							

1. See the “License Notes” section on page 3-9.

2. See the “VPN License and Feature Compatibility” section on page 3-12.

Table 3-4 shows the licenses for the ASA 5540.

**Table 3-4 ASA 5540 Adaptive Security Appliance License Features**

ASA 5540	Base License									
Firewall Licenses										
Botnet Traffic Filter <sup>1</sup>	Disabled		Optional Time-based license: Available							
Firewall Conns, Concurrent	400 K									
GTP/GPRS	Disabled		Optional license: Available							
Intercompany Media Engine <sup>1</sup>	Disabled		Optional license: Available							
Unified Communications Proxy Sessions <sup>1</sup>	2	Optional licenses:								
		24	50	100	250	500	750	1000	2000	
VPN Licenses <sup>2</sup>										
Adv. Endpoint Assessment	Disabled		Optional license: Available							
AnyConnect Essentials <sup>1</sup>	Disabled		Optional license: Available							
AnyConnect Mobile <sup>1</sup>	Disabled		Optional license: Available							
AnyConnect Premium SSL VPN Edition (sessions)	2	Optional Permanent or Time-based licenses:								
		10	25	50	100	250	500	750	1000	2500
		Optional Shared licenses: Participant or Server. For the Server, these licenses are available: <sup>1</sup>								
		500-50,000 in increments of 500					50,000-545,000 in increments of 1000			
IPSec VPN (sessions) <sup>1</sup>	5000 (max. 5000 combined IPSec and SSL VPN)									
VPN Load Balancing <sup>1</sup>	Supported									
General Licenses										
Encryption	Base (DES)		Optional license: Strong (3DES/AES)							
Failover	Active/Standby or Active/Active <sup>1</sup>									
Security Contexts	2	Optional licenses:								
		5	10	20	50					
VLANs, Maximum	200									

1. See the “License Notes” section on page 3-9.

2. See the “VPN License and Feature Compatibility” section on page 3-12.

Table 3-5 shows the licenses for the ASA 5550.

**Table 3-5 ASA 5550 Adaptive Security Appliance License Features**

ASA 5550	Base License										
Firewall Licenses											
Botnet Traffic Filter <sup>1</sup>	Disabled		Optional Time-based license: Available								
Firewall Conns, Concurrent	650 K										
GTP/GPRS	Disabled		Optional license: Available								
Intercompany Media Engine <sup>1</sup>	Disabled		Optional license: Available								
Unified Communications Proxy Sessions <sup>1</sup>	2	Optional licenses:									
		24	50	100	250	500	750	1000	2000	3000	
VPN Licenses <sup>2</sup>											
Adv. Endpoint Assessment	Disabled		Optional license: Available								
AnyConnect Essentials <sup>1</sup>	Disabled		Optional license: Available								
AnyConnect Mobile <sup>1</sup>	Disabled		Optional license: Available								
AnyConnect Premium SSL VPN Edition (sessions)	2	Optional Permanent or Time-based licenses:									
		10	25	50	100	250	500	750	1000	2500	5000
	Optional Shared licenses: Participant or Server. For the Server, these licenses are available: <sup>1</sup>										
	500-50,000 in increments of 500					50,000-545,000 in increments of 1000					
IPSec VPN (sessions) <sup>1</sup>	5000 (max. 5000 combined IPSec and SSL VPN)										
VPN Load Balancing <sup>1</sup>	Supported										
General Licenses											
Encryption	Base (DES)		Optional license: Strong (3DES/AES)								
Failover	Active/Standby or Active/Active <sup>1</sup>										
Security Contexts	2	Optional licenses:									
		5	10	20	50						
VLANs, Maximum	250										

1. See the “License Notes” section on page 3-9.

2. See the “VPN License and Feature Compatibility” section on page 3-12.

Table 3-6 shows the licenses for the ASA 5580.

**Table 3-6 ASA 5580 Adaptive Security Appliance License Features**

ASA 5580	Base License											
Firewall Licenses												
Botnet Traffic Filter <sup>1</sup>	Disabled		Optional Time-based license: Available									
Firewall Conns, Concurrent	5580-20: 1,000 K											
	5580-40: 2,000 K											
GTP/GPRS	Disabled		Optional license: Available									
Intercompany Media Engine <sup>1</sup>	Disabled		Optional license: Available									
Unified Communications Proxy Sessions <sup>1</sup>	2	Optional licenses:										
	24	50	100	250	500	750	1000	2000	3000	5000	10000 <sup>2</sup>	
VPN Licenses <sup>3</sup>												
Adv. Endpoint Assessment	Disabled		Optional license: Available									
AnyConnect Essentials <sup>1</sup>	Disabled		Optional license: Available									
AnyConnect Mobile <sup>1</sup>	Disabled		Optional license: Available									
AnyConnect Premium SSL VPN Edition (sessions)	2	Optional Permanent or Time-based licenses:										
		10	25	50	100	250	500	750	1000	2500	5000	
	Optional Shared licenses: Participant or Server. For the Server, these licenses are available: <sup>1</sup>											
	500-50,000 in increments of 500						50,000-545,000 in increments of 1000					
IPSec VPN (sessions) <sup>1</sup>	5000 (max. 5000 combined IPSec and SSL VPN)											
VPN Load Balancing <sup>1</sup>	Supported											
General Licenses												
Encryption	Base (DES)		Optional license: Strong (3DES/AES)									
Failover	Active/Standby or Active/Active <sup>1</sup>											
Security Contexts	2	Optional licenses:										
		5	10	20	50							
VLANs, Maximum	250											

1. See the “License Notes” section on page 3-9.

2. With the 10,000-session license, the total combined sessions can be 10,000, but the maximum number of Phone Proxy sessions is 5000.

3. See the “VPN License and Feature Compatibility” section on page 3-12.

## License Notes

Table 3-7 includes common footnotes shared by multiple tables in the “Licenses Per Model” section on page 3-2.

**Table 3-7**      **License Notes**

License	Notes
Active/Active Failover	You cannot use Active/Active failover and VPN; if you want to use VPN, use Active/Standby failover.
AnyConnect Essentials	<p>This license enables AnyConnect VPN client access to the adaptive security appliance. This license does not support browser-based (clientless) SSL VPN access or Cisco Secure Desktop. For these features, activate an AnyConnect Premium SSL VPN Edition license instead of the AnyConnect Essentials license.</p> <p><b>Note</b> With the AnyConnect Essentials license, VPN users can use a Web browser to log in, and download and start (WebLaunch) the AnyConnect client.</p> <p>The AnyConnect client software offers the same set of client features, whether it is enabled by this license or an AnyConnect Premium SSL VPN Edition license.</p> <p>The AnyConnect Essentials license cannot be active at the same time as the following licenses on a given adaptive security appliance: AnyConnect Premium SSL VPN Edition license (all types) or the Advanced Endpoint Assessment license. You can, however, run AnyConnect Essentials and AnyConnect Premium SSL VPN Edition licenses on different adaptive security appliances in the same network.</p> <p>By default, the adaptive security appliance uses the AnyConnect Essentials license, but you can disable it to use other licenses by using the <b>no anyconnect-essentials</b> command .</p> <p>See also the “VPN License and Feature Compatibility” section on page 3-12.</p>
AnyConnect Mobile	This license provides access to the AnyConnect Client for touch-screen mobile devices running Windows Mobile 5.0, 6.0, and 6.1. We recommend using this license if you want to support mobile access to AnyConnect 2.3 and later versions. This license requires activation of one of the following licenses to specify the total number of SSL VPN sessions permitted: AnyConnect Essentials or AnyConnect Premium SSL VPN Edition.
AnyConnect Premium SSL VPN Edition Shared	A shared license lets the adaptive security appliance act as a shared license server for multiple client adaptive security appliances. The shared license pool is large, but the maximum number of sessions used by each individual adaptive security appliance cannot exceed the maximum number listed for permanent licenses.
Botnet Traffic Filter	Requires a Strong Encryption (3DES/AES) License to download the dynamic database.
Combined IPSec and SSL VPN sessions	<ul style="list-style-type: none"> <li>Although the maximum IPSec and SSL VPN sessions add up to more than the maximum VPN sessions, the combined sessions should not exceed the VPN session limit. If you exceed the maximum VPN sessions, you can overload the adaptive security appliance, so be sure to size your network appropriately.</li> <li>If you start a clientless SSL VPN session and then start an AnyConnect client session from the portal, 1 session is used in total. However, if you start the AnyConnect client first (from a standalone client, for example) and then log into the clientless SSL VPN portal, then 2 sessions are used.</li> </ul>

**Table 3-7**      **License Notes (continued)**

License	Notes
Intercompany Media Engine	<p>When you enable the Intercompany Media Engine (IME) license, you can use TLS proxy sessions up to the TLS proxy limit. If you also have a Unified Communications (UC) license installed that is higher than the default TLS proxy limit, then the adaptive security appliance sets the limit to be the UC license limit plus an additional number of sessions depending on your model. You can manually configure the TLS proxy limit using the <b>tls-proxy maximum-sessions</b> command. To view the limits of your model, enter the <b>tls-proxy maximum-sessions ?</b> command. If you also install the UC license, then the TLS proxy sessions available for UC are also available for IME sessions. For example, if the configured limit is 1000 TLS proxy sessions, and you purchase a 750-session UC license, then the first 250 IME sessions do not affect the sessions available for UC. If you need more than 250 sessions for IME, then the remaining 750 sessions of the platform limit are used on a first-come, first-served basis by UC and IME.</p> <ul style="list-style-type: none"> <li>• For a license part number ending in “K8”, TLS proxy sessions are limited to 1000.</li> <li>• For a license part number ending in “K9”, the TLS proxy limit depends on your configuration and the platform model.</li> </ul> <p><b>Note</b>    K8 and K9 refer to whether the license is restricted for export: K8 is unrestricted, and K9 is restricted.</p> <p>You might also use SRTP encryption sessions for your connections:</p> <ul style="list-style-type: none"> <li>• For a K8 license, SRTP sessions are limited to 250.</li> <li>• For a K9 license, there is not limit.</li> </ul> <p><b>Note</b>    Only calls that require encryption/decryption for media are counted towards the SRTP limit; if passthrough is set for the call, even if both legs are SRTP, they do not count towards the limit.</p>

**Table 3-7**      **License Notes (continued)**

License	Notes
Unified Communications Proxy sessions	<p>The following applications use TLS proxy sessions for their connections. Each TLS proxy session used by these applications (and only these applications) is counted against the UC license limit:</p> <ul style="list-style-type: none"> <li>• Phone Proxy</li> <li>• Presence Federation Proxy</li> <li>• Encrypted Voice Inspection</li> </ul> <p>Other applications that use TLS proxy sessions do not count towards the UC limit, for example, Mobility Advantage Proxy (which does not require a license) and IME (which requires a separate IME license).</p> <p>Some UC applications might use multiple sessions for a connection. For example, if you configure a phone with a primary and backup Cisco Unified Communications Manager, there are 2 TLS proxy connections, so 2 UC Proxy sessions are used.</p> <p>You independently set the TLS proxy limit using the <b>tls-proxy maximum-sessions</b> command. To view the limits of your model, enter the <b>tls-proxy maximum-sessions ?</b> command. When you apply a UC license that is higher than the default TLS proxy limit, the adaptive security appliance automatically sets the TLS proxy limit to match the UC limit. The TLS proxy limit takes precedence over the UC license limit; if you set the TLS proxy limit to be less than the UC license, then you cannot use all of the sessions in your UC license.</p> <p><b>Note</b> For license part numbers ending in “K8” (for example, licenses under 250 users), TLS proxy sessions are limited to 1000. For license part numbers ending in “K9” (for example, licenses 250 users or larger), the TLS proxy limit depends on the configuration, up to the model limit. K8 and K9 refer to whether the license is restricted for export: K8 is unrestricted, and K9 is restricted.</p> <p>If you clear the configuration (using the <b>clear configure all</b> command, for example), then the TLS proxy limit is set to the default for your model; if this default is lower than the UC license limit, then you see an error message to use the <b>tls-proxy maximum-sessions</b> command to raise the limit again. If you use failover and enter the <b>write standby</b> command on the primary unit to force a configuration synchronization, the <b>clear configure all</b> command is generated on the secondary unit automatically, so you may see the warning message on the secondary unit. Because the configuration synchronization restores the TLS proxy limit set on the primary unit, you can ignore the warning.</p> <p>You might also use SRTP encryption sessions for your connections:</p> <ul style="list-style-type: none"> <li>• For K8 licenses, SRTP sessions are limited to 250.</li> <li>• For K9 licenses, there is not limit.</li> </ul> <p><b>Note</b> Only calls that require encryption/decryption for media are counted towards the SRTP limit; if passthrough is set for the call, even if both legs are SRTP, they do not count towards the limit.</p>
VPN load balancing	Requires a Strong Encryption (3DES/AES) License.

## VPN License and Feature Compatibility

Table 3-8 shows how the VPN licenses and features can combine.

For a detailed list of the features supported by the AnyConnect Essentials license and AnyConnect Premium license, see *AnyConnect Secure Mobility Client Features, Licenses, and OSs*:

- Version 3.0:  
[http://www.cisco.com/en/US/docs/security/vpn\\_client/anyconnect/anyconnect30/feature/guide/anyconnect30features.html](http://www.cisco.com/en/US/docs/security/vpn_client/anyconnect/anyconnect30/feature/guide/anyconnect30features.html)
- Version 2.5:  
[http://www.cisco.com/en/US/docs/security/vpn\\_client/anyconnect/anyconnect25/feature/guide/anyconnect25features.html](http://www.cisco.com/en/US/docs/security/vpn_client/anyconnect/anyconnect25/feature/guide/anyconnect25features.html)

**Table 3-8 VPN License and Feature Compatibility**

Supported with:	Enable one of the following licenses: <sup>1</sup>	
	AnyConnect Essentials	AnyConnect Premium SSL VPN Edition
AnyConnect Mobile	Yes	Yes
Advanced Endpoint Assessment	No	Yes
AnyConnect Premium SSL VPN Edition Shared	No	Yes
Client-based SSL VPN	Yes	Yes
Browser-based (clientless) SSL VPN	No	Yes
IPsec VPN	Yes	Yes
VPN Load Balancing	Yes	Yes
Cisco Secure Desktop	No	Yes

1. You can only have one license type active, either the AnyConnect Essentials license or the AnyConnect Premium license. By default, the adaptive security appliance includes an AnyConnect Premium license for 2 sessions. If you install the AnyConnect Essentials license, then it is used by default. See the **no anyconnect-essentials** command to enable the Premium license instead.

## Information About Feature Licenses

A license specifies the options that are enabled on a given adaptive security appliance. It is represented by an activation key that is a 160-bit (5 32-bit words or 20 bytes) value. This value encodes the serial number (an 11 character string) and the enabled features.

This section includes the following topics:

- [Preinstalled License, page 3-13](#)
- [Permanent License, page 3-13](#)
- [Time-Based Licenses, page 3-13](#)
- [Shared SSL VPN Licenses, page 3-15](#)
- [Failover Licenses \(8.3\(1\) and Later\), page 3-20](#)
- [Licenses FAQ, page 3-21](#)

## Preinstalled License

By default, your adaptive security appliance ships with a license already installed. This license might be the Base License, to which you want to add more licenses, or it might already have all of your licenses installed, depending on what you ordered and what your vendor installed for you. See the [“Viewing Your Current License” section on page 3-24](#) section to determine which licenses you have installed.

## Permanent License

You can have one permanent activation key installed. The permanent activation key includes all licensed features in a single key. If you also install time-based licenses, the adaptive security appliance combines the permanent and time-based licenses into a running license. See the [“How Permanent and Time-Based Licenses Combine” section on page 3-14](#) for more information about how the adaptive security appliance combines the licenses.

## Time-Based Licenses

In addition to permanent licenses, you can purchase time-based licenses or receive an evaluation license that has a time-limit. For example, you might buy a time-based SSL VPN license to handle short-term surges in the number of concurrent SSL VPN users, or you might order a Botnet Traffic Filter time-based license that is valid for 1 year.

This section includes the following topics:

- [Time-Based License Activation Guidelines, page 3-13](#)
- [How the Time-Based License Timer Works, page 3-13](#)
- [How Permanent and Time-Based Licenses Combine, page 3-14](#)
- [Stacking Time-Based Licenses, page 3-15](#)
- [Time-Based License Expiration, page 3-15](#)

### Time-Based License Activation Guidelines

- You can install multiple time-based licenses, including multiple licenses for the same feature. However, only one time-based license per feature can be *active* at a time. The inactive license remains installed, and ready for use. For example, if you install a 1000-session SSL VPN license, and a 2500-session SSL VPN license, then only one of these licenses can be active.
- If you activate an evaluation license that has multiple features in the key, then you cannot also activate another time-based license for one of the included features. For example, if an evaluation license includes the Botnet Traffic Filter and a 1000-session SSL VPN license, you cannot also activate a standalone time-based 2500-session SSL VPN license.

### How the Time-Based License Timer Works

- The timer for the time-based license starts counting down when you activate it on the adaptive security appliance.
- If you stop using the time-based license before it times out, then the timer halts. The timer only starts again when you reactivate the time-based license.

- If the time-based license is active, and you shut down the adaptive security appliance, then the timer continues to count down. If you intend to leave the adaptive security appliance in a shut down state for an extended period of time, then you should deactivate the time-based license before you shut down.

**Note**

We suggest you do not change the system clock after you install the time-based license. If you set the clock to be a later date, then if you reload, the adaptive security appliance checks the system clock against the original installation time, and assumes that more time has passed than has actually been used. If you set the clock back, and the actual running time is greater than the time between the original installation time and the system clock, then the license immediately expires after a reload.

## How Permanent and Time-Based Licenses Combine

When you activate a time-based license, then features from both permanent and time-based licenses combine to form the running license. How the permanent and time-based licenses combine depends on the type of license. [Table 3-9](#) lists the combination rules for each feature license.

**Note**

Even when the permanent license is used, if the time-based license is active, it continues to count down.

**Table 3-9** *Time-Based License Combination Rules*

Time-Based Feature	Combined License Rule
SSL VPN Sessions	The higher value is used, either time-based or permanent. For example, if the permanent license is 1000 sessions, and the time-based license is 2500 sessions, then 2500 sessions are enabled. Typically, you will not install a time-based license that has less capability than the permanent license, but if you do so, then the permanent license is used.
Unified Communications Proxy Sessions	The time-based license sessions are added to the permanent sessions, up to the platform limit. For example, if the permanent license is 2500 sessions, and the time-based license is 1000 sessions, then 3500 sessions are enabled for as long as the time-based license is active.
Security Contexts	The time-based license contexts are added to the permanent contexts, up to the platform limit. For example, if the permanent license is 10 contexts, and the time-based license is 20 contexts, then 30 contexts are enabled for as long as the time-based license is active.
Botnet Traffic Filter	There is no permanent Botnet Traffic Filter license available; the time-based license is used.
All Others	The higher value is used, either time-based or permanent. For licenses that have a status of enabled or disabled, then the license with the enabled status is used. For licenses with numerical tiers, the higher value is used. Typically, you will not install a time-based license that has less capability than the permanent license, but if you do so, then the permanent license is used.

To view the combined license, see the [“Viewing Your Current License”](#) section on page 3-24.

## Stacking Time-Based Licenses

In many cases, you might need to renew your time-based license and have a seamless transition from the old license to the new one. For features that are only available with a time-based license, it is especially important that the license not expire before you can apply the new license. The adaptive security appliance allows you to *stack* time-based licenses so you do not have to worry about the license expiring or about losing time on your licenses because you installed the new one early.

When you install an identical time-based license as one already installed, then the licenses are combined, and the duration equals the combined duration.

For example:

1. You install a 52-week Botnet Traffic Filter license, and use the license for 25 weeks (27 weeks remain).
2. You then purchase another 52-week Botnet Traffic Filter license. When you install the second license, the licenses combine to have a duration of 79 weeks (52 weeks plus 27 weeks).

Similarly:

1. You install an 8-week 1000-session SSL VPN license, and use it for 2 weeks (6 weeks remain).
2. You then install another 8-week 1000-session license, and the licenses combine to be 1000-sessions for 14 weeks (8 weeks plus 6 weeks).

If the licenses are not identical (for example, a 1000-session SSL VPN license vs. a 2500-session license), then the licenses are *not* combined. Because only one time-based license per feature can be active, only one of the licenses can be active. See the [“Activating or Deactivating Keys” section on page 3-30](#) for more information about activating licenses.

Although non-identical licenses do not combine, when the current license expires, the adaptive security appliance automatically activates an installed license of the same feature if available. See the [“Time-Based License Expiration” section on page 3-15](#) for more information.

## Time-Based License Expiration

When the current license for a feature expires, the adaptive security appliance automatically activates an installed license of the same feature if available. If there are no other time-based licenses available for the feature, then the permanent license is used.

If you have more than one additional time-based license installed for a feature, then the adaptive security appliance uses the first license it finds; which license is used is not user-configurable and depends on internal operations. If you prefer to use a different time-based license than the one the adaptive security appliance activated, then you must manually activate the license you prefer. See the [“Activating or Deactivating Keys” section on page 3-30](#).

For example, you have a time-based 2500-session SSL VPN license (active), a time-based 1000-session SSL VPN license (inactive), and a permanent 500-session SSL VPN license. While the 2500-session license expires, the adaptive security appliance activates the 1000-session license. After the 1000-session license expires, the adaptive security appliance uses the 500-session permanent license.

## Shared SSL VPN Licenses

A shared license lets you purchase a large number of SSL VPN sessions and share the sessions as needed among a group of adaptive security appliances by configuring one of the adaptive security appliances as a shared licensing server, and the rest as shared licensing participants. This section describes how a shared license works and includes the following topics:

- [Information About the Shared Licensing Server and Participants, page 3-16](#)
- [Communication Issues Between Participant and Server, page 3-17](#)
- [Information About the Shared Licensing Backup Server, page 3-17](#)
- [Failover and Shared Licenses, page 3-18](#)
- [Maximum Number of Participants, page 3-19](#)

## Information About the Shared Licensing Server and Participants

The following steps describe how shared licenses operate:

1. Decide which adaptive security appliance should be the shared licensing server, and purchase the shared licensing server license using that device serial number.
2. Decide which adaptive security appliances should be shared licensing participants, including the shared licensing backup server, and obtain a shared licensing participant license for each device, using each device serial number.
3. (Optional) Designate a second adaptive security appliance as a shared licensing backup server. You can only specify one backup server.

---

**Note** The shared licensing backup server only needs a participant license.

---

4. Configure a shared secret on the shared licensing server; any participants with the shared secret can use the shared license.
5. When you configure the adaptive security appliance as a participant, it registers with the shared licensing server by sending information about itself, including the local license and model information.

---

**Note** The participant needs to be able to communicate with the server over the IP network; it does not have to be on the same subnet.

---

6. The shared licensing server responds with information about how often the participant should poll the server.
7. When a participant uses up the sessions of the local license, it sends a request to the shared licensing server for additional sessions in 50-session increments.
8. The shared licensing server responds with a shared license. The total sessions used by a participant cannot exceed the maximum sessions for the platform model.

---

**Note** The shared licensing server can also participate in the shared license pool. It does not need a participant license as well as the server license to participate.

---

- a. If there are not enough sessions left in the shared license pool for the participant, then the server responds with as many sessions as available.
  - b. The participant continues to send refresh messages requesting more sessions until the server can adequately fulfill the request.
9. When the load is reduced on a participant, it sends a message to the server to release the shared sessions.

**Note**

The adaptive security appliance uses SSL between the server and participant to encrypt all communications.

## Communication Issues Between Participant and Server

See the following guidelines for communication issues between the participant and server:

- If a participant fails to send a refresh after 3 times the refresh interval, then the server releases the sessions back into the shared license pool.
- If the participant cannot reach the license server to send the refresh, then the participant can continue to use the shared license it received from the server for up to 24 hours.
- If the participant is still not able to communicate with a license server after 24 hours, then the participant releases the shared license, even if it still needs the sessions. The participant leaves existing connections established, but cannot accept new connections beyond the license limit.
- If a participant reconnects with the server before 24 hours expires, but after the server expired the participant sessions, then the participant needs to send a new request for the sessions; the server responds with as many sessions as can be reassigned to that participant.

## Information About the Shared Licensing Backup Server

The shared licensing backup server must register successfully with the main shared licensing server before it can take on the backup role. When it registers, the main shared licensing server syncs server settings as well as the shared license information with the backup, including a list of registered participants and the current license usage. The main server and backup server sync the data at 10 second intervals. After the initial sync, the backup server can successfully perform backup duties, even after a reload.

When the main server goes down, the backup server takes over server operation. The backup server can operate for up to 30 continuous days, after which the backup server stops issuing sessions to participants, and existing sessions time out. Be sure to reinstate the main server within that 30-day period. Critical-level syslog messages are sent at 15 days, and again at 30 days.

When the main server comes back up, it syncs with the backup server, and then takes over server operation.

When the backup server is not active, it acts as a regular participant of the main shared licensing server.

**Note**

When you first launch the main shared licensing server, the backup server can only operate independently for 5 days. The operational limit increases day-by-day, until 30 days is reached. Also, if the main server later goes down for any length of time, the backup server operational limit decrements day-by-day. When the main server comes back up, the backup server starts to increment again day-by-day. For example, if the main server is down for 20 days, with the backup server active during that time, then the backup server will only have a 10-day limit left over. The backup server “recharges” up to the maximum 30 days after 20 more days as an inactive backup. This recharging function is implemented to discourage misuse of the shared license.

## Failover and Shared Licenses

This section describes how shared licenses interact with failover and includes the following topics:

- “Failover and Shared License Servers” section on page 3-18
- “Failover and Shared License Participants” section on page 3-19

### Failover and Shared License Servers

This section describes how the main server and backup server interact with failover. Because the shared licensing server is also performing normal duties as the adaptive security appliance, including performing functions such as being a VPN gateway and firewall, then you might need to configure failover for the main and backup shared licensing servers for increased reliability.

**Note**

---

The backup server mechanism is separate from, but compatible with, failover.

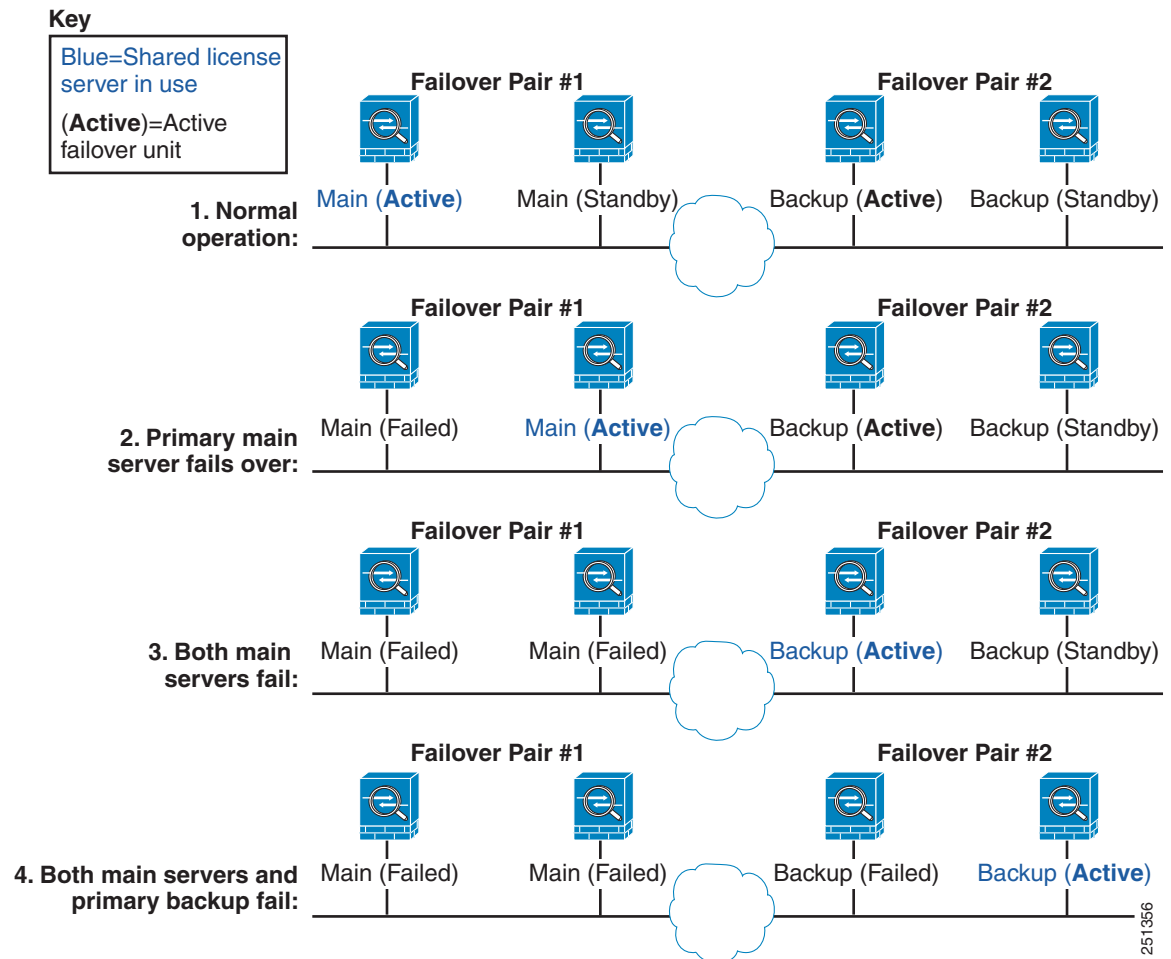

---

Shared licenses are supported only in single context mode, so Active/Active failover is not supported.

---

For Active/Standby failover, the primary unit acts as the main shared licensing server, and the standby unit acts as the main shared licensing server after failover. The standby unit does *not* act as the backup shared licensing server. Instead, you can have a second pair of units acting as the backup server, if desired.

For example, you have a network with 2 failover pairs. Pair #1 includes the main licensing server. Pair #2 includes the backup server. When the primary unit from Pair #1 goes down, the standby unit immediately becomes the new main licensing server. The backup server from Pair #2 never gets used. Only if both units in Pair #1 go down does the backup server in Pair #2 come into use as the shared licensing server. If Pair #1 remains down, and the primary unit in Pair #2 goes down, then the standby unit in Pair #2 comes into use as the shared licensing server (see [Figure 3-1](#)).

**Figure 3-1** Failover and Shared License Servers

The standby backup server shares the same operating limits as the primary backup server; if the standby unit becomes active, it continues counting down where the primary unit left off. See the [“Information About the Shared Licensing Backup Server”](#) section on page 3-17 for more information.

### Failover and Shared License Participants

For participant pairs, both units register with the shared licensing server using separate participant IDs. The active unit syncs its participant ID with the standby unit. The standby unit uses this ID to generate a transfer request when it switches to the active role. This transfer request is used to move the shared sessions from the previously active unit to the new active unit.

### Maximum Number of Participants

The adaptive security appliance does not limit the number of participants for the shared license; however, a very large shared network could potentially affect the performance on the licensing server. In this case, you can increase the delay between participant refreshes, or you can create two shared networks.

## Failover Licenses (8.3(1) and Later)

In Version 8.3(1) and later, failover units do not require the same license on each unit. For earlier versions, see the licensing document for your version.

This section includes the following topics:

- [Failover License Requirements, page 3-20](#)
- [How Failover Licenses Combine, page 3-20](#)
- [Loss of Communication Between Failover Units, page 3-21](#)
- [Upgrading Failover Pairs, page 3-21](#)

### Failover License Requirements

- Failover units do not require the same license on each unit.  
Older versions of adaptive security appliance software required that the licenses match on each unit. Starting with Version 8.3(1), you no longer need to install identical licenses. Typically, you buy a license only for the primary unit; for Active/Standby failover, the secondary unit inherits the primary license when it becomes active. If you have licenses on both units, they combine into a single running failover cluster license.
- For the ASA 5505 and 5510 adaptive security appliances, both units require the Security Plus license; the Base license does not support failover, so you cannot enable failover on a standby unit that only has the Base license.

### How Failover Licenses Combine

For failover pairs, the licenses on each unit are combined into a single running failover cluster license. For Active/Active failover, the license usage of the two units combined cannot exceed the failover cluster license.

If you buy separate licenses for the primary and secondary unit, then the combined license uses the following rules:

- For licenses that have numerical tiers, such as the number of sessions, the values from both the primary and secondary licenses are combined up to the platform limit. If both licenses in use are time-based, then the licenses count down simultaneously.

For example, you have two ASA 5520 adaptive security appliances with 500 SSL VPN sessions each; because the platform limit is 750, the combined license allows 750 SSL VPN sessions.

**Note** In the above example, if the SSL VPN licenses are time-based, you might want to disable one of the licenses so you do not “waste” a 500 session license from which you can only use 250 sessions because of the platform limit.

Or you have two ASA 5540 adaptive security appliances, one with 20 contexts and the other with 10 contexts; the combined license allows 30 contexts. For Active/Active failover, for example, one unit can use 18 contexts and the other unit can use 12 contexts, for a total of 30; the combined usage cannot exceed the failover cluster license.

- For licenses that have a status of enabled or disabled, then the license with the enabled status is used.

- For time-based licenses that are enabled or disabled (and do not have numerical tiers), the duration is the combined duration of both licenses. The primary unit counts down its license first, and when it expires, the secondary unit starts counting down its license. This rule also applies to Active/Active failover, even though both units are actively operating.

For example, if you have 48 weeks left on the Botnet Traffic Filter license on both units, then the combined duration is 96 weeks.

To view the combined license, see the [“Viewing Your Current License” section on page 3-24](#).

## Loss of Communication Between Failover Units

If the failover units lose communication for more than 30 days, then each unit reverts to the license installed locally. During the 30-day grace period, the combined running license continues to be used by both units.

If you restore communication during the 30-day grace period, then for time-based licenses, the time elapsed is subtracted from the primary license; if the primary license becomes expired, only then does the secondary license start to count down.

If you do not restore communication during the 30-day period, then for time-based licenses, time is subtracted from both primary and secondary licenses, if installed. They are treated as two separate licenses and do not benefit from the failover combined license. The time elapsed includes the 30-day grace period.

For example:

1. You have a 52-week Botnet Traffic Filter license installed on both units. The combined running license allows a total duration of 104 weeks.
2. The units operate as a failover unit for 10 weeks, leaving 94 weeks on the combined license (42 weeks on the primary, and 52 weeks on the secondary).
3. If the units lose communication (for example the primary unit fails over to the secondary unit), the secondary unit continues to use the combined license, and continues to count down from 94 weeks.
4. The time-based license behavior depends on when communication is restored:
  - Within 30 days—The time elapsed is subtracted from the primary unit license. In this case, communication is restored after 4 weeks. Therefore, 4 weeks are subtracted from the primary license leaving 90 weeks combined (38 weeks on the primary, and 52 weeks on the secondary).
  - After 30 days—The time elapsed is subtracted from both units. In this case, communication is restored after 6 weeks. Therefore, 6 weeks are subtracted from both the primary and secondary licenses, leaving 84 weeks combined (36 weeks on the primary, and 46 weeks on the secondary).

## Upgrading Failover Pairs

Because failover pairs do not require the same license on both units, you can apply new licenses to each unit without any downtime. If you apply a permanent license that requires a reload (see [Table 3-10 on page 3-30](#)), then you can fail over to the other unit while you reload. If both units require reloading, then you can reload them separately so you have no downtime.

## Licenses FAQ

- Q.** Can I activate multiple time-based licenses, for example, SSL VPN and Botnet Traffic Filter?

- A.** Yes. You can use one time-based license per feature at a time.
- Q.** Can I “stack” time-based licenses so that when the time limit runs out, it will automatically use the next license?
- A.** Yes. For identical licenses, the time limit is combined when you install multiple time-based licenses. For non-identical licenses (for example, a 1000-session SSL VPN license and a 2500-session license), the adaptive security appliance automatically activates the next time-based license it finds for the feature.
- Q.** Can I install a new permanent license while maintaining an active time-based license?
- A.** Yes. Activating a permanent license does not affect time-based licenses.
- Q.** For failover, can I use a shared licensing server as the primary unit, and the shared licensing backup server as the secondary unit?
- A.** No. The secondary unit has the same running license as the primary unit; in the case of the shared licensing server, they require a server license. The backup server requires a participant license. The backup server can be in a separate failover pair of two backup servers.
- Q.** Do I need to buy the same licenses for the secondary unit in a failover pair?
- A.** No. Starting with Version 8.3(1), you do not have to have matching licenses on both units. Typically, you buy a license only for the primary unit; the secondary unit inherits the primary license when it becomes active. In the case where you also have a separate license on the secondary unit (for example, if you purchased matching licenses for pre-8.3 software), the licenses are combined into a running failover cluster license, up to the model limits.
- Q.** Can I use a time-based or permanent SSL VPN license in addition to a shared SSL VPN license?
- A.** Yes. The shared license is used only after the sessions from the locally installed license (time-based or permanent) are used up. **Note:** On the shared licensing server, the permanent SSL VPN license is not used; you can however use a time-based license at the same time as the shared licensing server license. In this case, the time-based license sessions are available for local SSL VPN sessions only; they cannot be added to the shared licensing pool for use by participants.

## Guidelines and Limitations

See the following guidelines for activation keys.

### Context Mode Guidelines

- In multiple context mode, apply the activation key in the system execution space.
- Shared licenses are not supported in multiple context mode.

### Firewall Mode Guidelines

All license types are available in both routed and transparent mode.

### Failover Guidelines

- Shared licenses are not supported in Active/Active mode. See the [“Failover and Shared Licenses” section on page 3-18](#) for more information.
- Failover units do not require the same license on each unit.

Older versions of adaptive security appliance software required that the licenses match on each unit. Starting with Version 8.3(1), you no longer need to install identical licenses. Typically, you buy a license only for the primary unit; for Active/Standby failover, the secondary unit inherits the primary license when it becomes active. If you have licenses on both units, they combine into a single running failover cluster license.

---

**Note** Failover units do require the same RAM on both units.

---

- For the ASA 5505 and 5510 adaptive security appliances, both units require the Security Plus license; the Base license does not support failover, so you cannot enable failover on a standby unit that only has the Base license.

### Upgrade and Downgrade Guidelines

Your activation key remains compatible if you upgrade to the latest version from any previous version. However, you might have issues if you want to maintain downgrade capability:

- Downgrading to Version 8.1 or earlier—After you upgrade, if you activate additional feature licenses that were introduced *before* 8.2, then the activation key continues to be compatible with earlier versions if you downgrade. However if you activate feature licenses that were introduced in 8.2 or later, then the activation key is not backwards compatible. If you have an incompatible license key, then see the following guidelines:
  - If you previously entered an activation key in an earlier version, then the adaptive security appliance uses that key (without any of the new licenses you activated in Version 8.2 or later).
  - If you have a new system and do not have an earlier activation key, then you need to request a new activation key compatible with the earlier version.
- Downgrading to Version 8.2 or earlier—Version 8.3 introduced more robust time-based key usage as well as failover license changes:
  - If you have more than one time-based activation key active, when you downgrade, only the most recently activated time-based key can be active. Any other keys are made inactive. If the last time-based license is for a feature introduced in 8.3, then that license still remains the active license even though it cannot be used in earlier versions. Reenter the permanent key or a valid time-based key.
  - If you have mismatched licenses on a failover pair, then downgrading will disable failover. Even if the keys are matching, the license used will no longer be a combined license.
  - If you have one time-based license installed, but it is for a feature introduced in 8.3, then after you downgrade, that time-based license remains active. You need to reenter the permanent key to disable the time-based license.

### Additional Guidelines and Limitations

- The activation key is not stored in your configuration file; it is stored as a hidden file in flash memory.
- The activation key is tied to the serial number of the device. Feature licenses cannot be transferred between devices (except in the case of a hardware failure). If you have to replace your device due to a hardware failure, contact the Cisco Licensing Team to have your existing license transferred to the new serial number. The Cisco Licensing Team will ask for the Product Authorization Key reference number and existing serial number.
- Once purchased, you cannot return a license for a refund or for an upgraded license.

- Although you can activate all license types, some features are incompatible with each other; for example, multiple context mode and VPN. In the case of the AnyConnect Essentials license, the license is incompatible with the following licenses: full SSL VPN license, shared SSL VPN license, and Advanced Endpoint Assessment license. By default, the AnyConnect Essentials license is used instead of the above licenses, but you can disable the AnyConnect Essentials license in the configuration to restore use of the other licenses using the **no anyconnect-essentials** command.

## Viewing Your Current License

This section describes how to view your current license, and for time-based activation keys, how much time the license has left.

### Detailed Steps

Command	Purpose
<b>show activation-key [detail]</b>	This command shows the permanent license, active time-based licenses, and the running license, which is a combination of the permanent license and active time-based licenses. The <b>detail</b> keyword also shows inactive time-based licenses.
<b>Example:</b> hostname# show activation-key detail	For failover units, this command also shows the “Failover cluster” license, which is the combined keys of the primary and secondary units.

### Examples

#### Example 3-1 Standalone Unit Output for show activation-key

The following is sample output from the **show activation-key** command for a standalone unit that shows the running license (the combined permanent license and time-based licenses), as well as each active time-based license:

```
hostname# show activation-key
```

```
Serial Number: JMX1232L11M
Running Permanent Activation Key: 0xce06dc6b 0x8a7b5ab7 0xa1e21dd4 0xd2c4b8b8 0xc4594f9c
Running Timebased Activation Key: 0xa821d549 0x35725fe4 0xc918b97b 0xce0b987b 0x47c7c285
Running Timebased Activation Key: 0xyadayad2 0xyadayad2 0xyadayad2 0xyadayad2 0xyadayad2
```

```

```

### Example 3-3 Primary Unit Output in a Failover Pair for show activation-key detail

The following is sample output from the **show activation-key detail** command for the primary failover unit that shows:

- The primary unit license (the combined permanent license and time-based licenses).
- The “Failover Cluster” license, which is the combined licenses from the primary and secondary units. This is the license that is actually running on the adaptive security appliance. The values in this license that reflect the combination of the primary and secondary licenses are in bold.
- The primary unit permanent license.
- The primary unit installed time-based licenses (active and inactive).

```
hostname# show activation-key detail
```

```
Serial Number: P3000000171
```

```
Running Permanent Activation Key: 0xce06dc6b 0x8a7b5ab7 0xa1e21dd4 0xd2c4b8b8 0xc4594f9c
```

```
Running Timebased Activation Key: 0xa821d549 0x35725fe4 0xc918b97b 0xce0b987b 0x47c7c285
```

The flash permanent activation key is the SAME as the running permanent key.

## Obtaining an Activation Key

To obtain an activation key, you need a Product Authorization Key, which you can purchase from your Cisco account representative. You need to purchase a separate Product Activation Key for each feature license. For example, if you have the Base License, you can purchase separate keys for Advanced Endpoint Assessment and for additional SSL VPN sessions.

After obtaining the Product Authorization Keys, register them on Cisco.com by performing the following steps.

### Detailed Steps

- 
- Step 1** Obtain the serial number for your adaptive security appliance by entering the following command.
- ```
hostname# show activation-key
```
- Step 2** Access one of the following URLs.
- Use the following website if you are a registered user of Cisco.com:  
<http://www.cisco.com/go/license>
  - Use the following website if you are not a registered user of Cisco.com:  
<http://www.cisco.com/go/license/public>
- Step 3** Enter the following information, when prompted:
- Product Authorization Key (if you have multiple keys, enter one of the keys first. You have to enter each key as a separate process.)

- The serial number of your adaptive security appliance
- Your email address

An activation key is automatically generated and sent to the email address that you provide. This key includes all features you have registered so far for permanent licenses. For time-based licenses, each license has a separate activation key.

- Step 4** If you have additional Product Authorization Keys, repeat [Step 3](#) for each Product Authorization Key. After you enter all of the Product Authorization Keys, the final activation key provided includes all of the permanent features you registered.

## Activating or Deactivating Keys

This section describes how to enter a new activation key, and how to activate and deactivate time-based keys.

### Prerequisites

- If you are already in multiple context mode, enter the activation key in the system execution space.
- Some permanent licenses require you to reload the adaptive security appliance after you activate them. [Table 3-10](#) lists the licenses that require reloading.

**Table 3-10**      **Permanent License Reloading Requirements**

| Model                 | License Action Requiring Reload                                                        |
|-----------------------|----------------------------------------------------------------------------------------|
| ASA 5505 and ASA 5510 | Changing between the Base and Security Plus license.                                   |
| All models            | Changing the Encryption license.                                                       |
| All models            | Downgrading any permanent license (for example, going from 10 contexts to 2 contexts). |

### Limitations and Restrictions

Your activation key remains compatible if you upgrade to the latest version from any previous version. However, you might have issues if you want to maintain downgrade capability:

- Downgrading to Version 8.1 or earlier—After you upgrade, if you activate additional feature licenses that were introduced *before* 8.2, then the activation key continues to be compatible with earlier versions if you downgrade. However if you activate feature licenses that were introduced in 8.2 *or later*, then the activation key is not backwards compatible. If you have an incompatible license key, then see the following guidelines:
  - If you previously entered an activation key in an earlier version, then the adaptive security appliance uses that key (without any of the new licenses you activated in Version 8.2 or later).
  - If you have a new system and do not have an earlier activation key, then you need to request a new activation key compatible with the earlier version.
- Downgrading to Version 8.2 or earlier—Version 8.3 introduced more robust time-based key usage as well as failover license changes:

- If you have more than one time-based activation key active, when you downgrade, only the most recently activated time-based key can be active. Any other keys are made inactive.
- If you have mismatched licenses on a failover pair, then downgrading will disable failover. Even if the keys are matching, the license used will no longer be a combined license.

### Detailed Steps

|        | Command                                                                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>activation-key</b> <i>key</i> [ <b>activate</b>   <b>deactivate</b> ]<br><br><b>Example:</b><br><pre>hostname# activation-key 0xd11b3d48 0xa80a4c0a 0x48e0fd1c 0xb0443480 0x843fc490</pre> | <p>Applies an activation key to the adaptive security appliance. The <i>key</i> is a five-element hexadecimal string with one space between each element. The leading 0x specifier is optional; all values are assumed to be hexadecimal.</p> <p>You can install one permanent key, and multiple time-based keys. If you enter a new permanent key, it overwrites the already installed one.</p> <p>The <b>activate</b> and <b>deactivate</b> keywords are available for time-based keys only. If you do not enter any value, <b>activate</b> is the default. The last time-based key that you activate for a given feature is the active one. To deactivate any active time-based key, enter the <b>deactivate</b> keyword. If you enter a key for the first time, and specify <b>deactivate</b>, then the key is installed on the adaptive security appliance in an inactive state. See the <a href="#">“Time-Based Licenses” section on page 3-13</a> for more information.</p> |
| Step 2 | <p>(Might be required.)</p> <p><b>reload</b></p> <p><b>Example:</b></p> <pre>hostname# reload</pre>                                                                                           | <p>Reloads the adaptive security appliance. Some permanent licenses require you to reload the adaptive security appliance after entering the new activation key. See <a href="#">Table 3-10 on page 3-30</a> for a list of licenses that need reloading. If you need to reload, you will see the following message:</p> <p>WARNING: The running activation key was not updated with the requested key. The flash activation key was updated with the requested key, and will become active after the next reload.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Configuring a Shared License

This section describes how to configure the shared licensing server and participants. For more information about shared licenses, see the [“Shared SSL VPN Licenses” section on page 3-15](#).

This section includes the following topics:

- [Configuring the Shared Licensing Server, page 3-32](#)
- [Configuring the Shared Licensing Backup Server \(Optional\), page 3-33](#)
- [Configuring the Shared Licensing Participant, page 3-34](#)
- [Monitoring the Shared License, page 3-35](#)

## Configuring the Shared Licensing Server

This section describes how to configure the adaptive security appliance to be a shared licensing server.

### Prerequisites

The server must have a shared licensing server key.

### Detailed Steps

|        | Command                                                                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>license-server secret</b> <i>secret</i><br><br><b>Example:</b><br>hostname(config)# license-server secret farscape                                                                                                                       | Sets the shared secret, a string between 4 and 128 ASCII characters. Any participant with this secret can use the licensing server.                                                                                               |
| Step 2 | (Optional)<br><b>license-server refresh-interval</b> <i>seconds</i><br><br><b>Example:</b><br>hostname(config)# license-server refresh-interval 100                                                                                         | Sets the refresh interval between 10 and 300 seconds; this value is provided to participants to set how often they should communicate with the server. The default is 30 seconds.                                                 |
| Step 3 | (Optional)<br><b>license-server port</b> <i>port</i><br><br><b>Example:</b><br>hostname(config)# license-server port 40000                                                                                                                  | Sets the port on which the server listens for SSL connections from participants, between 1 and 65535. The default is TCP port 50554.                                                                                              |
| Step 4 | (Optional)<br><b>license-server backup</b> <i>address backup-id serial_number [ha-backup-id ha_serial_number]</i><br><br><b>Example:</b><br>hostname(config)# license-server backup 10.1.1.2 backup-id JMX0916L0Z4 ha-backup-id JMX1378N0W3 | Identifies the backup server IP address and serial number. If the backup server is part of a failover pair, identify the standby unit serial number as well. You can only identify 1 backup server and its optional standby unit. |
| Step 5 | <b>license-server enable</b> <i>interface_name</i><br><br><b>Example:</b><br>hostname(config)# license-server enable inside                                                                                                                 | Enables this unit to be the shared licensing server. Specify the interface on which participants contact the server. You can repeat this command for as many interfaces as desired.                                               |

## Examples

The following example sets the shared secret, changes the refresh interval and port, configures a backup server, and enables this unit as the shared licensing server on the inside interface and dmz interface.

```
hostname(config)# license-server secret farscape
hostname(config)# license-server refresh-interval 100
hostname(config)# license-server port 40000
hostname(config)# license-server backup 10.1.1.2 backup-id JMX0916L0Z4 ha-backup-id
JMX1378N0W3
hostname(config)# license-server enable inside
hostname(config)# license-server enable dmz
```

## What to Do Next

See the [“Configuring the Shared Licensing Backup Server \(Optional\)”](#) section on page 3-33, or the [“Configuring the Shared Licensing Participant”](#) section on page 3-34.

# Configuring the Shared Licensing Backup Server (Optional)

This section enables a shared license participant to act as the backup server if the main server goes down.

## Prerequisites

The backup server must have a shared licensing participant key.

## Detailed Steps

|        | Command                                                                                                                                                     | Purpose                                                                                                                                                                                    |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>license-server address address secret secret [port port]</b><br><br><b>Example:</b><br>hostname(config)# license-server address 10.1.1.1 secret farscape | Identifies the shared licensing server IP address and shared secret. If you changed the default port in the server configuration, set the port for the backup server to match.             |
| Step 2 | <b>license-server backup enable interface_name</b><br><br><b>Example:</b><br>hostname(config)# license-server backup enable inside                          | Enables this unit to be the shared licensing backup server. Specify the interface on which participants contact the server. You can repeat this command for as many interfaces as desired. |

## Examples

The following example identifies the license server and shared secret, and enables this unit as the backup shared license server on the inside interface and dmz interface.

```
hostname(config)# license-server address 10.1.1.1 secret farscape
hostname(config)# license-server backup enable inside
hostname(config)# license-server backup enable dmz
```

## What to Do Next

See the [“Configuring the Shared Licensing Participant”](#) section on page 3-34.

# Configuring the Shared Licensing Participant

This section configures a shared licensing participant to communicate with the shared licensing server.

## Prerequisites

The participant must have a shared licensing participant key.

## Detailed Steps

|        | Command                                                                                                                                                     | Purpose                                                                                                                                                                      |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>license-server address address secret secret [port port]</b><br><br><b>Example:</b><br>hostname(config)# license-server address 10.1.1.1 secret farscape | Identifies the shared licensing server IP address and shared secret. If you changed the default port in the server configuration, set the port for the participant to match. |
| Step 2 | (Optional)<br><b>license-server backup address address</b><br><br><b>Example:</b><br>hostname(config)# license-server backup address 10.1.1.2               | If you configured a backup server, enter the backup server address.                                                                                                          |

## Examples

The following example sets the license server IP address and shared secret, as well as the backup license server IP address:

```
hostname(config)# license-server address 10.1.1.1 secret farscape
hostname(config)# license-server backup address 10.1.1.2
```

## Monitoring the Shared License

To monitor the shared license, enter one of the following commands.

| Command                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>show shared license</b> [ <b>detail</b>   <b>client</b> ]<br>[ <i>hostname</i> ]   <b>backup</b> | Shows shared license statistics. Optional keywords are available only for the licensing server: the <b>detail</b> keyword shows statistics per participant. To limit the display to one participant, use the <b>client</b> keyword. The <b>backup</b> keyword shows information about the backup server.<br><br>To clear the shared license statistics, enter the <b>clear shared license</b> command. |
| <b>show activation-key</b>                                                                          | Shows the licenses installed on the adaptive security appliance. The <b>show version</b> command also shows license information.                                                                                                                                                                                                                                                                       |
| <b>show vpn-sessiondb</b>                                                                           | Shows license information about VPN sessions.                                                                                                                                                                                                                                                                                                                                                          |

### Examples

The following is sample output from the **show shared license** command on the license participant:

```
hostname> show shared license
Primary License Server : 10.3.32.20
  Version              : 1
  Status               : Inactive

Shared license utilization:
SSLVPN:
  Total for network    :    5000
  Available            :    5000
  Utilized             :         0
This device:
  Platform limit       :        250
  Current usage        :         0
  High usage           :         0
Messages Tx/Rx/Error:
  Registration         : 0 / 0 / 0
  Get                  : 0 / 0 / 0
  Release              : 0 / 0 / 0
  Transfer             : 0 / 0 / 0
```

The following is sample output from the **show shared license detail** command on the license server:

```
hostname> show shared license detail
Backup License Server Info:

Device ID              : ABCD
Address                : 10.1.1.2
Registered             : NO
HA peer ID            : EFGH
Registered             : NO

## Feature History for Licensing

[Table 3-11](#) lists the release history for this feature.

**Table 3-11**      *Feature History for Licensing*

| Feature Name                                              | Releases | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Increased Connections and VLANs                           | 7.0(5)   | Increased the following limits: <ul style="list-style-type: none"> <li>• ASA5510 Base license connections from 32000 to 5000; VLANs from 0 to 10.</li> <li>• ASA5510 Security Plus license connections from 64000 to 130000; VLANs from 10 to 25.</li> <li>• ASA5520 connections from 130000 to 280000; VLANs from 25 to 100.</li> <li>• ASA5540 connections from 280000 to 400000; VLANs from 100 to 200.</li> </ul> |
| SSL VPN Licenses                                          | 7.1(1)   | SSL VPN licenses were introduced.                                                                                                                                                                                                                                                                                                                                                                                     |
| Increased SSL VPN Licenses                                | 7.2(1)   | A 5000-user SSL VPN license was introduced for the ASA 5550 and above.                                                                                                                                                                                                                                                                                                                                                |
| Increased interfaces for the Base license on the ASA 5510 | 7.2(2)   | For the Base license on the ASA 5510, the maximum number of interfaces was increased from 3 plus a management interface to unlimited interfaces.                                                                                                                                                                                                                                                                      |

**Table 3-11**      *Feature History for Licensing (continued)*

| Feature Name                                                    | Releases | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Increased VLANs                                                 | 7.2(2)   | <p>The maximum number of VLANs for the Security Plus license on the ASA 5505 adaptive security appliance was increased from 5 (3 fully functional; 1 failover; one restricted to a backup interface) to 20 fully functional interfaces. In addition, the number of trunk ports was increased from 1 to 8. Now there are 20 fully functional interfaces, you do not need to use the backup interface command to cripple a backup ISP interface; you can use a fully-functional interface for it. The backup interface command is still useful for an Easy VPN configuration.</p> <p>VLAN limits were also increased for the ASA 5510 adaptive security appliance (from 10 to 50 for the Base license, and from 25 to 100 for the Security Plus license), the ASA 5520 adaptive security appliance (from 100 to 150), the ASA 5550 adaptive security appliance (from 200 to 250).</p>                                                                                |
| Gigabit Ethernet Support for the ASA 5510 Security Plus License | 7.2(3)   | <p>The ASA 5510 adaptive security appliance now supports Gigabit Ethernet (1000 Mbps) for the Ethernet 0/0 and 0/1 ports with the Security Plus license. In the Base license, they continue to be used as Fast Ethernet (100 Mbps) ports. Ethernet 0/2, 0/3, and 0/4 remain as Fast Ethernet ports for both licenses.</p> <p><b>Note</b>    The interface names remain Ethernet 0/0 and Ethernet 0/1.</p> <p>Use the <b>speed</b> command to change the speed on the interface and use the <b>show interface</b> command to see what speed is currently configured for each interface.</p>                                                                                                                                                                                                                                                                                                                                                                         |
| Advanced Endpoint Assessment License                            | 8.0(2)   | <p>The Advanced Endpoint Assessment license was introduced. As a condition for the completion of a Cisco AnyConnect or clientless SSL VPN connections, the remote computer scans for a greatly expanded collection of antivirus and antispyware applications, firewalls, operating systems, and associated updates. It also scans for any registry entries, filenames, and process names that you specify. It sends the scan results to the adaptive security appliance. The adaptive security appliance uses both the user login credentials and the computer scan results to assign a Dynamic Access Policy (DAP).</p> <p>With an Advanced Endpoint Assessment License, you can enhance Host Scan by configuring an attempt to update noncompliant computers to meet version requirements.</p> <p>Cisco can provide timely updates to the list of applications and versions that Host Scan supports in a package that is separate from Cisco Secure Desktop.</p> |
| VPN Load Balancing for the ASA 5510                             | 8.0(2)   | VPN load balancing is now supported on the ASA 5510 Security Plus license.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 3-11**      *Feature History for Licensing (continued)*

| Feature Name                                  | Releases      | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AnyConnect for Mobile License                 | 8.0(3)        | The AnyConnect for Mobile license was introduced. It lets Windows mobile devices connect to the adaptive security appliance using the AnyConnect client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Time-based Licenses                           | 8.0(4)/8.1(2) | Support for time-based licenses was introduced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Increased VLANs for the ASA 5580              | 8.1(2)        | The number of VLANs supported on the ASA 5580 are increased from 100 to 250.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Unified Communications Proxy Sessions license | 8.0(4)        | <p>The UC Proxy sessions license was introduced. Phone Proxy, Presence Federation Proxy, and Encrypted Voice Inspection applications use TLS proxy sessions for their connections. Each TLS proxy session is counted against the UC license limit. All of these applications are licensed under the UC Proxy umbrella, and can be mixed and matched.</p> <p>This feature is not available in Version 8.1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Botnet Traffic Filter License                 | 8.2(1)        | The Botnet Traffic Filter license was introduced. The Botnet Traffic Filter protects against malware network activity by tracking connections to known bad domains and IP addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| AnyConnect Essentials License                 | 8.2(1)        | <p>The AnyConnect Essentials License was introduced. This license enables AnyConnect VPN client access to the adaptive security appliance. This license does not support browser-based SSL VPN access or Cisco Secure Desktop. For these features, activate an AnyConnect Premium SSL VPN Edition license instead of the AnyConnect Essentials license.</p> <p><b>Note</b> With the AnyConnect Essentials license, VPN users can use a Web browser to log in, and download and start (WebLaunch) the AnyConnect client.</p> <p>The AnyConnect client software offers the same set of client features, whether it is enabled by this license or an AnyConnect Premium SSL VPN Edition license.</p> <p>The AnyConnect Essentials license cannot be active at the same time as the following licenses on a given adaptive security appliance: AnyConnect Premium SSL VPN Edition license (all types) or the Advanced Endpoint Assessment license. You can, however, run AnyConnect Essentials and AnyConnect Premium SSL VPN Edition licenses on different adaptive security appliances in the same network.</p> <p>By default, the adaptive security appliance uses the AnyConnect Essentials license, but you can disable it to use other licenses by using the <b>no anyconnect-essentials</b> command.</p> |

| Feature Name                                                                       | Releases | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Shared Licenses for SSL VPN                                                        | 8.2(1)   | Shared licenses for SSL VPN were introduced. Multiple adaptive security appliances can share a pool of SSL VPN sessions on an as-needed basis.                                                                                                                                                                                                                                                                                                                                                                                                              |
| Mobility Proxy application no longer requires Unified Communications Proxy license | 8.2(2)   | The Mobility Proxy no longer requires the UC Proxy license.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Non-identical failover licenses                                                    | 8.3(1)   | Failover licenses no longer need to be identical on each unit. The license used for both units is the combined license from the primary and secondary units.<br><br>The following commands were modified: <b>show activation-key</b> and <b>show version</b> .                                                                                                                                                                                                                                                                                              |
| Stackable time-based licenses                                                      | 8.3(1)   | Time-based licenses are now stackable. In many cases, you might need to renew your time-based license and have a seamless transition from the old license to the new one. For features that are only available with a time-based license, it is especially important that the license not expire before you can apply the new license. The adaptive security appliance allows you to <i>stack</i> time-based licenses so you do not have to worry about the license expiring or about losing time on your licenses because you installed the new one early. |
| Intercompany Media Engine License                                                  | 8.3(1)   | The IME license was introduced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Multiple time-based licenses active at the same time                               | 8.3(1)   | You can now install multiple time-based licenses, and have one license per feature active at a time.<br><br>The following commands were modified: <b>show activation-key</b> and <b>show version</b> .                                                                                                                                                                                                                                                                                                                                                      |
| Discrete activation and deactivation of time-based licenses.                       | 8.3(1)   | You can now activate or deactivate time-based licenses using a command.<br><br>The following commands was modified: <b>activation-key [activate   deactivate]</b> .                                                                                                                                                                                                                                                                                                                                                                                         |

## CHAPTER 4

# Configuring the Transparent or Routed Firewall

This chapter describes how to configure the firewall mode, routed or transparent, and how to customize transparent firewall operation.

**Note**

In multiple context mode, you cannot set the firewall mode separately for each context; you can only set the firewall mode for the entire adaptive security appliance.

This chapter includes the following sections:

- [Configuring the Firewall Mode, page 4-1](#)
- [Configuring ARP Inspection for the Transparent Firewall, page 4-8](#)
- [Customizing the MAC Address Table for the Transparent Firewall, page 4-12](#)
- [Firewall Mode Examples, page 4-15](#)

## Configuring the Firewall Mode

This section describes routed and transparent firewall mode, and how to set the mode. This section includes the following topics:

- [Information About the Firewall Mode, page 4-1](#)
- [Licensing Requirements for the Firewall Mode, page 4-4](#)
- [Default Settings, page 4-4](#)
- [Guidelines and Limitations, page 4-5](#)
- [Setting the Firewall Mode, page 4-7](#)
- [Feature History for Firewall Mode, page 4-8](#)

## Information About the Firewall Mode

This section describes routed and transparent firewall mode and includes the following topics:

- [Information About Routed Firewall Mode, page 4-2](#)
- [Information About Transparent Firewall Mode, page 4-2](#)

## Information About Routed Firewall Mode

In routed mode, the adaptive security appliance is considered to be a router hop in the network. It can use OSPF or RIP (in single context mode). Routed mode supports many interfaces. Each interface is on a different subnet. You can share interfaces between contexts.

The adaptive security appliance acts as a router between connected networks, and each interface requires an IP address on a different subnet. In single context mode, the routed firewall supports OSPF, EIGRP, and RIP. Multiple context mode supports static routes only. We recommend using the advanced routing capabilities of the upstream and downstream routers instead of relying on the adaptive security appliance for extensive routing needs.

## Information About Transparent Firewall Mode

Traditionally, a firewall is a routed hop and acts as a default gateway for hosts that connect to one of its screened subnets. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices.

This section describes transparent firewall mode and includes the following topics:

- [Transparent Firewall Network, page 4-2](#)
- [Allowing Layer 3 Traffic, page 4-2](#)
- [Allowed MAC Addresses, page 4-2](#)
- [Passing Traffic Not Allowed in Routed Mode, page 4-3](#)
- [BPDU Handling, page 4-3](#)
- [MAC Address vs. Route Lookups, page 4-3](#)
- [Using the Transparent Firewall in Your Network, page 4-4](#)

### Transparent Firewall Network

The adaptive security appliance connects the same network on its inside and outside interfaces. Because the firewall is not a routed hop, you can easily introduce a transparent firewall into an existing network.

### Allowing Layer 3 Traffic

IPv4 and IPv6 traffic is allowed through the transparent firewall automatically from a higher security interface to a lower security interface, without an access list. ARPs are allowed through the transparent firewall in both directions without an access list. ARP traffic can be controlled by ARP inspection. For Layer 3 traffic travelling from a low to a high security interface, an extended access list is required on the low security interface. See [Chapter 13, “Adding an Extended Access List,”](#) or [Chapter 17, “Adding an IPv6 Access List,”](#) for more information.

### Allowed MAC Addresses

The following destination MAC addresses are allowed through the transparent firewall. Any MAC address not on this list is dropped.

- TRUE broadcast destination MAC address equal to FFFF.FFFF.FFFF
- IPv4 multicast MAC addresses from 0100.5E00.0000 to 0100.5EFE.FFFF
- IPv6 multicast MAC addresses from 3333.0000.0000 to 3333.FFFF.FFFF
- BPDU multicast address equal to 0100.0CCC.CCCD

- AppleTalk multicast MAC addresses from 0900.0700.0000 to 0900.07FF.FFFF

## Passing Traffic Not Allowed in Routed Mode

In routed mode, some types of traffic cannot pass through the adaptive security appliance even if you allow it in an access list. The transparent firewall, however, can allow almost any traffic through using either an extended access list (for IP traffic) or an EtherType access list (for non-IP traffic).

### Note

The transparent mode adaptive security appliance does not pass CDP packets, or any packets that do not have a valid EtherType greater than or equal to 0x600. For example, you cannot pass IS-IS packets. An exception is made for BPDUs, which are supported.

For example, you can establish routing protocol adjacencies through a transparent firewall; you can allow OSPF, RIP, EIGRP, or BGP traffic through based on an extended access list. Likewise, protocols like HSRP or VRRP can pass through the adaptive security appliance.

Non-IP traffic (for example AppleTalk, IPX, BPDUs, and MPLS) can be configured to go through using an EtherType access list.

For features that are not directly supported on the transparent firewall, you can allow traffic to pass through so that upstream and downstream routers can support the functionality. For example, by using an extended access list, you can allow DHCP traffic (instead of the unsupported DHCP relay feature) or multicast traffic such as that created by IP/TV.

## BPDUs Handling

To prevent loops using the spanning tree protocol, BPDUs are passed by default. To block BPDUs, you need to configure an EtherType access list to deny them.

## MAC Address vs. Route Lookups

When the adaptive security appliance runs in transparent mode, the outgoing interface of a packet is determined by performing a MAC address lookup instead of a route lookup.

Route lookups, however, are necessary for the following traffic types:

- Traffic originating on the adaptive security appliance—For example, if your syslog server is located on a remote network, you must use a static route so the adaptive security appliance can reach that subnet.
- Voice over IP (VoIP) traffic with inspection enabled, and the endpoint is at least one hop away from the adaptive security appliance—For example, if you use the transparent firewall between a CCM and an H.323 gateway, and there is a router between the transparent firewall and the H.323 gateway, then you need to add a static route on the adaptive security appliance for the H.323 gateway for successful call completion.
- VoIP or DNS traffic with NAT and inspection enabled—To successfully translate the IP address inside VoIP and DNS packets, the adaptive security appliance needs to perform a route lookup. Unless the host is on a directly-connected network, then you need to add a static route on the adaptive security appliance for the real host address that is embedded in the packet.

### Using the Transparent Firewall in Your Network

Figure 4-1 shows a typical transparent firewall network where the outside devices are on the same subnet as the inside devices. The inside router and hosts appear to be directly connected to the outside router.

**Figure 4-1** *Transparent Firewall Network*

## Licensing Requirements for the Firewall Mode

The following table shows the licensing requirements for this feature.

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Default Settings

The default mode is routed mode.

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

- The firewall mode is set for the entire system and all contexts; you cannot set the mode individually for each context.
- For multiple context mode, set the mode in the system execution space.
- When you change modes, the adaptive security appliance clears the running configuration because many commands are not supported for both modes. This action removes any contexts from running. If you then re-add a context that has an existing configuration that was created for the wrong mode, the context configuration might not work correctly. Be sure to recreate your context configurations for the correct mode before you re-add them, or add new contexts with new paths for the new configurations.

### Transparent Firewall Guidelines

Follow these guidelines when planning your transparent firewall network:

- For IPv4, a management IP address is required for both management traffic and for traffic to pass through the adaptive security appliance. For multiple context mode, an IP address is required for each context.

Unlike routed mode, which requires an IP address for each interface, a transparent firewall has an IP address assigned to the entire device. The adaptive security appliance uses this IP address as the source address for packets originating on the adaptive security appliance, such as system messages or AAA communications.

The management IP address must be on the same subnet as the connected network. You cannot set the subnet to a host subnet (255.255.255.255).

For IPv6, at a minimum you need to configure link-local addresses for each interface for through traffic. For full functionality, including the ability to manage the adaptive security appliance, you need to configure a global IP address for the device.

You can configure an IP address (both IPv4 and IPv6) for the Management 0/0 or Management 0/1 management-only interface. This IP address can be on a separate subnet from the main management IP address.

- The transparent adaptive security appliance uses an inside interface and an outside interface only. If your platform includes a dedicated management interface, you can also configure the management interface or subinterface for management traffic only.

In single mode, you can only use two data interfaces (and the dedicated management interface, if available) even if your security appliance includes more than two interfaces.

**Note**

In transparent firewall mode, the management interface updates the MAC address table in the same manner as a data interface; therefore you should not connect both a management and a data interface to the same switch unless you configure one of the switch ports as a routed port (by default Cisco Catalyst switches share a MAC address for all VLAN switch ports). Otherwise, if traffic arrives on the management interface from the physically-connected switch, then the adaptive security appliance updates the MAC address table to use the *management* interface to access the switch, instead of the data interface. This action causes a temporary traffic interruption; the adaptive security appliance will not re-update the MAC address table for packets from the switch to the data interface for at least 30 seconds for security reasons.

- Each directly connected network must be on the same subnet.
- Do not specify the adaptive security appliance management IP address as the default gateway for connected devices; devices need to specify the router on the other side of the adaptive security appliance as the default gateway.
- For multiple context mode, each context must use different interfaces; you cannot share an interface across contexts.
- For multiple context mode, each context typically uses a different subnet. You can use overlapping subnets, but your network topology requires router and NAT configuration to make it possible from a routing standpoint.

**IPv6 Guidelines**

Supports IPv6.

**Additional Guidelines and Limitations**

- When you change modes, the adaptive security appliance clears the running configuration because many commands are not supported for both modes. The startup configuration remains unchanged. If you reload without saving, then the startup configuration is loaded, and the mode reverts back to the original setting. See the [“Setting the Firewall Mode” section on page 4-7](#) for information about backing up your configuration file.
- If you download a text configuration to the adaptive security appliance that changes the mode with the **firewall transparent** command, be sure to put the command at the top of the configuration; the adaptive security appliance changes the mode as soon as it reads the command and then continues reading the configuration you downloaded. If the command appears later in the configuration, the adaptive security appliance clears all the preceding lines in the configuration. See the [“Downloading Software or Configuration Files to Flash Memory” section on page 76-3](#) for information about downloading text files.

**Unsupported Features in Transparent Mode**

[Table 4-1](#) lists the features are not supported in transparent mode.

**Table 4-1**      *Unsupported Features in Transparent Mode*

| Feature                             | Description                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dynamic DNS                         | —                                                                                                                                                                                                                                                                                                                                                                  |
| DHCP relay                          | The transparent firewall can act as a DHCP server, but it does not support the DHCP relay commands. DHCP relay is not required because you can allow DHCP traffic to pass through using two extended access lists: one that allows DHCP requests from the inside interface to the outside, and one that allows the replies from the server in the other direction. |
| Dynamic routing protocols           | You can, however, add static routes for traffic originating on the adaptive security appliance. You can also allow dynamic routing protocols through the adaptive security appliance using an extended access list.                                                                                                                                                |
| Multicast IP routing                | You can allow multicast traffic through the adaptive security appliance by allowing it in an extended access list.                                                                                                                                                                                                                                                 |
| QoS                                 | —                                                                                                                                                                                                                                                                                                                                                                  |
| VPN termination for through traffic | The transparent firewall supports site-to-site VPN tunnels for management connections only. It does not terminate VPN connections for traffic through the adaptive security appliance. You can pass VPN traffic through the security appliance using an extended access list, but it does not terminate non-management connections. SSL VPN is also not supported. |

## Setting the Firewall Mode

This section describes how to change the firewall mode.

### Note

We recommend that you set the firewall mode before you perform any other configuration because changing the firewall mode clears the running configuration.

### Prerequisites

When you change modes, the adaptive security appliance clears the running configuration (see the [“Guidelines and Limitations”](#) section on page 4-5 for more information).

- If you already have a populated configuration, be sure to back up your configuration before changing the mode; you can use this backup for reference when creating your new configuration. See the [“Backing Up Configuration Files”](#) section on page 76-8.
- Use the CLI at the console port to change the mode. If you use any other type of session, including the ASDM Command Line Interface tool or SSH, you will be disconnected when the configuration is cleared, and you will have to reconnect to the adaptive security appliance using the console port in any case.

## Detailed Steps

| Command                                                              | Purpose                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>firewall transparent</b>                                          | Sets the firewall mode to transparent. Enter this command in the system execution space for multiple context mode. To change the mode to routed, enter the <b>no firewall transparent</b> command.                                               |
| <b>Example:</b><br><pre>hostname(config)# firewall transparent</pre> | This command also appears in each context configuration for informational purposes only; you cannot enter this command in a context.<br><br><b>Note</b> You are not prompted to confirm the firewall mode change; the change occurs immediately. |

## Feature History for Firewall Mode

Table 4-2 lists the release history for this feature.

**Table 4-2** Feature History for Firewall Mode

| Feature Name              | Releases | Feature Information                                                                                                                                                                                                                                                  |
|---------------------------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Transparent firewall mode | 7.0(1)   | A transparent firewall is a Layer 2 firewall that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices.<br><br>The following commands were introduced: <b>firewall transparent</b> , <b>show firewall</b> . |

## Configuring ARP Inspection for the Transparent Firewall

This section describes ARP inspection and how to enable it and includes the following topics:

- [Information About ARP Inspection, page 4-8](#)
- [Licensing Requirements for ARP Inspection, page 4-9](#)
- [Default Settings, page 4-9](#)
- [Guidelines and Limitations, page 4-9](#)
- [Configuring ARP Inspection, page 4-9](#)
- [Monitoring ARP Inspection, page 4-11](#)
- [Feature History for ARP Inspection, page 4-11](#)

## Information About ARP Inspection

By default, all ARP packets are allowed through the adaptive security appliance. You can control the flow of ARP packets by enabling ARP inspection.

When you enable ARP inspection, the adaptive security appliance compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.
- If there is a mismatch between the MAC address, the IP address, or the interface, then the adaptive security appliance drops the packet.
- If the ARP packet does not match any entries in the static ARP table, then you can set the adaptive security appliance to either forward the packet out all interfaces (flood), or to drop the packet.

**Note** The dedicated management interface, if present, never floods packets even if this parameter is set to flood.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a “man-in-the-middle” attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.

## Licensing Requirements for ARP Inspection

The following table shows the licensing requirements for this feature.

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Default Settings

By default, all ARP packets are allowed through the adaptive security appliance.

If you enable ARP inspection, the default setting is to flood non-matching packets.

## Guidelines and Limitations

### Context Mode Guidelines

- Supported in single and multiple context mode.
- In multiple context mode, configure ARP inspection within each context.

### Firewall Mode Guidelines

Supported only in transparent firewall mode. Routed mode is not supported.

## Configuring ARP Inspection

This section describes how to configure ARP inspection and includes the following topics:

- [Task Flow for Configuring ARP Inspection, page 4-10](#)
- [Adding a Static ARP Entry, page 4-10](#)
- [Enabling ARP Inspection, page 4-11](#)

Task Flow for Configuring ARP Inspection

To configure ARP Inspection, perform the following steps:

- Step 1

Add static ARP entries according to the [“Adding a Static ARP Entry” section on page 4-10](#). ARP inspection compares ARP packets with static ARP entries in the ARP table, so static ARP entries are required for this feature.
- Step 2

Enable ARP inspection according to the [“Enabling ARP Inspection” section on page 4-11](#).

Adding a Static ARP Entry

ARP inspection compares ARP packets with static ARP entries in the ARP table. Although hosts identify a packet destination by an IP address, the actual delivery of the packet on Ethernet relies on the Ethernet MAC address. When a router or host wants to deliver a packet on a directly connected network, it sends an ARP request asking for the MAC address associated with the IP address, and then delivers the packet to the MAC address according to the ARP response. The host or router keeps an ARP table so it does not have to send ARP requests for every packet it needs to deliver. The ARP table is dynamically updated whenever ARP responses are sent on the network, and if an entry is not used for a period of time, it times out. If an entry is incorrect (for example, the MAC address changes for a given IP address), the entry times out before it can be updated.

Note

The transparent firewall uses dynamic ARP entries in the ARP table for traffic to and from the adaptive security appliance, such as management traffic.

Detailed Steps

| Command                                                                               | Purpose                  |
|---------------------------------------------------------------------------------------|--------------------------|
| <code>arp interface_name ip_address mac_address</code>                                | Adds a static ARP entry. |
| <b>Example:</b><br><code>hostname(config)# arp outside 10.1.1.1 0009.7cbe.2100</code> |                          |

Examples

For example, to allow ARP responses from the router at 10.1.1.1 with the MAC address 0009.7cbe.2100 on the outside interface, enter the following command:

```
hostname(config)# arp outside 10.1.1.1 0009.7cbe.2100
```

## What to Do Next

Enable ARP inspection according to the [“Enabling ARP Inspection” section on page 4-11](#).

## Enabling ARP Inspection

This section describes how to enable ARP inspection.

### Detailed Steps

| Command                                                                                         | Purpose                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>arp-inspection</b> <i>interface_name</i> <b>enable</b><br>[ <b>flood</b>   <b>no-flood</b> ] | Enables ARP inspection.<br><br>The <b>flood</b> keyword forwards non-matching ARP packets out all interfaces, and <b>no-flood</b> drops non-matching packets.                                |
| <b>Example:</b><br>hostname(config)# arp-inspection outside<br>enable no-flood                  | <b>Note</b> The default setting is to flood non-matching packets. To restrict ARP through the adaptive security appliance to only static entries, then set this command to <b>no-flood</b> . |

### Examples

For example, to enable ARP inspection on the outside interface, and to drop all non-matching ARP packets, enter the following command:

```
hostname(config)# arp-inspection outside enable no-flood
```

## Monitoring ARP Inspection

To monitor ARP inspection, perform the following task:

| Command                    | Purpose                                                          |
|----------------------------|------------------------------------------------------------------|
| <b>show arp-inspection</b> | Shows the current settings for ARP inspection on all interfaces. |

## Feature History for ARP Inspection

[Table 4-3](#) lists the release history for this feature.

**Table 4-3** Feature History for ARP Inspection

| Feature Name   | Releases | Feature Information                                                                                                                                                                                                                                   |
|----------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ARP inspection | 7.0(1)   | ARP inspection compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table.<br><br>The following commands were introduced: <b>arp</b> , <b>arp-inspection</b> , and <b>show arp-inspection</b> . |

# Customizing the MAC Address Table for the Transparent Firewall

This section describes the MAC address table and includes the following topics:

- [Information About the MAC Address Table, page 4-12](#)
- [Licensing Requirements for the MAC Address Table, page 4-12](#)
- [Default Settings, page 4-13](#)
- [Guidelines and Limitations, page 4-13](#)
- [Configuring the MAC Address Table, page 4-13](#)
- [Monitoring the MAC Address Table, page 4-15](#)
- [Feature History for the MAC Address Table, page 4-15](#)

## Information About the MAC Address Table

The adaptive security appliance learns and builds a MAC address table in a similar way as a normal bridge or switch: when a device sends a packet through the adaptive security appliance, the adaptive security appliance adds the MAC address to its table. The table associates the MAC address with the source interface so that the adaptive security appliance knows to send any packets addressed to the device out the correct interface.

The ASA 5505 adaptive security appliance includes a built-in switch; the switch MAC address table maintains the MAC address-to-switch port mapping for traffic within each VLAN. This section discusses the bridge MAC address table, which maintains the MAC address-to-VLAN interface mapping for traffic that passes between VLANs.

Because the adaptive security appliance is a firewall, if the destination MAC address of a packet is not in the table, the adaptive security appliance does not flood the original packet on all interfaces as a normal bridge does. Instead, it generates the following packets for directly connected devices or for remote devices:

- Packets for directly connected devices—The adaptive security appliance generates an ARP request for the destination IP address, so that the adaptive security appliance can learn which interface receives the ARP response.
- Packets for remote devices—The adaptive security appliance generates a ping to the destination IP address so that the adaptive security appliance can learn which interface receives the ping reply.

The original packet is dropped.

## Licensing Requirements for the MAC Address Table

The following table shows the licensing requirements for this feature.

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Default Settings

The default timeout value for dynamic MAC address table entries is 5 minutes.

By default, each interface, including the optional management interface, automatically learns the MAC addresses of entering traffic, and the adaptive security appliance adds corresponding entries to the MAC address table.

## Guidelines and Limitations

### Context Mode Guidelines

- Supported in single and multiple context mode.
- In multiple context mode, configure the MAC address table within each context.

### Firewall Mode Guidelines

Supported only in transparent firewall mode. Routed mode is not supported.

### Additional Guidelines

In transparent firewall mode, the management interface updates the MAC address table in the same manner as a data interface; therefore you should not connect both a management and a data interface to the same switch unless you configure one of the switch ports as a routed port (by default Cisco Catalyst switches share a MAC address for all VLAN switch ports). Otherwise, if traffic arrives on the management interface from the physically-connected switch, then the adaptive security appliance updates the MAC address table to use the *management* interface to access the switch, instead of the data interface. This action causes a temporary traffic interruption; the adaptive security appliance will not re-update the MAC address table for packets from the switch to the data interface for at least 30 seconds for security reasons.

## Configuring the MAC Address Table

This section describes how you can customize the MAC address table and includes the following sections:

- [Adding a Static MAC Address, page 4-13](#)
- [Setting the MAC Address Timeout, page 4-14](#)
- [Disabling MAC Address Learning, page 4-14](#)

## Adding a Static MAC Address

Normally, MAC addresses are added to the MAC address table dynamically as traffic from a particular MAC address enters an interface. You can add static MAC addresses to the MAC address table if desired. One benefit to adding static entries is to guard against MAC spoofing. If a client with the same MAC address as a static entry attempts to send traffic to an interface that does not match the static entry,

then the adaptive security appliance drops the traffic and generates a system message. When you add a static ARP entry (see the [“Adding a Static ARP Entry” section on page 4-10](#)), a static MAC address entry is automatically added to the MAC address table.

To add a static MAC address to the MAC address table, enter the following command:

| Command                                                                                | Purpose                                                                                |
|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <b>mac-address-table static</b> <i>interface_name</i> <i>mac_address</i>               | Adds a static MAC address entry.<br>The <i>interface_name</i> is the source interface. |
| <b>Example:</b><br>hostname(config)# mac-address-table static<br>inside 0009.7cbe.2100 |                                                                                        |

## Setting the MAC Address Timeout

The default timeout value for dynamic MAC address table entries is 5 minutes, but you can change the timeout. To change the timeout, enter the following command:

| Command                                                                 | Purpose                                                                                                                                 |
|-------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>mac-address-table aging-time</b> <i>timeout_value</i>                | Sets the MAC address entry timeout.<br>The <i>timeout_value</i> (in minutes) is between 5 and 720 (12 hours). 5 minutes is the default. |
| <b>Example:</b><br>hostname(config)# mac-address-table<br>aging-time 10 |                                                                                                                                         |

## Disabling MAC Address Learning

By default, each interface automatically learns the MAC addresses of entering traffic, and the adaptive security appliance adds corresponding entries to the MAC address table. You can disable MAC address learning if desired, however, unless you statically add MAC addresses to the table, no traffic can pass through the adaptive security appliance.

To disable MAC address learning, enter the following command:

| Command                                                       | Purpose                                                                                                                                                                                             |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mac-learn</b> <i>interface_name</i> <b>disable</b>         | Disables MAC address learning.<br>The <b>no</b> form of this command reenables MAC address learning. The <b>clear configure mac-learn</b> command reenables MAC address learning on all interfaces. |
| <b>Example:</b><br>hostname(config)# mac-learn inside disable |                                                                                                                                                                                                     |

## Monitoring the MAC Address Table

You can view the entire MAC address table (including static and dynamic entries for both interfaces), or you can view the MAC address table for an interface. To view the MAC address table, enter the following command:

| Command                                              | Purpose                      |
|------------------------------------------------------|------------------------------|
| <code>show mac-address-table [interface_name]</code> | Shows the MAC address table. |

### Examples

The following is sample output from the **show mac-address-table** command that shows the entire table:

```
hostname# show mac-address-table
interface      mac address      type      Time Left
-----
outside        0009.7cbe.2100    static    -
inside         0010.7cbe.6101    static    -
inside         0009.7cbe.5101    dynamic   10
```

The following is sample output from the **show mac-address-table** command that shows the table for the inside interface:

```
hostname# show mac-address-table inside
interface      mac address      type      Time Left
-----
inside         0010.7cbe.6101    static    -
inside         0009.7cbe.5101    dynamic   10
```

## Feature History for the MAC Address Table

Table 4-4 lists the release history for this feature.

**Table 4-4** Feature History for the MAC Address Table

| Feature Name      | Releases | Feature Information                                                                                                                                                                                                                             |
|-------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAC address table | 7.0(1)   | Transparent firewall mode uses a MAC address table.<br><br>The following commands were introduced:<br><b>mac-address-table static</b> , <b>mac-address-table aging-time</b> ,<br><b>mac-learn disable</b> , and <b>show mac-address-table</b> . |

## Firewall Mode Examples

This section includes examples of how traffic moves through the adaptive security appliance and includes the following topics:

- [How Data Moves Through the Security Appliance in Routed Firewall Mode, page 4-16](#)
- [How Data Moves Through the Transparent Firewall, page 4-22](#)

## How Data Moves Through the Security Appliance in Routed Firewall Mode

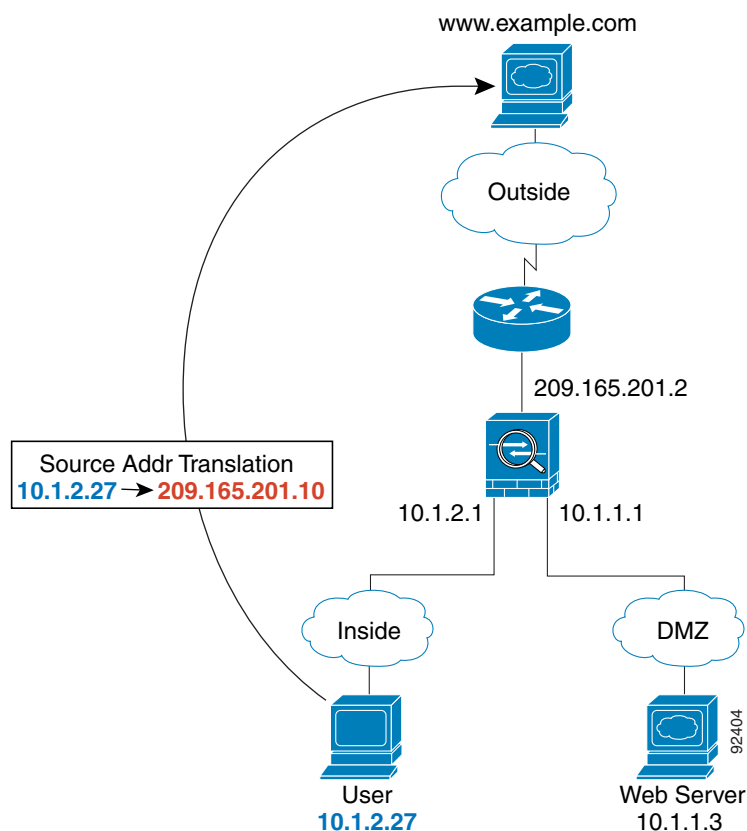

This section describes how data moves through the adaptive security appliance in routed firewall mode and includes the following topics:

- [An Inside User Visits a Web Server, page 4-16](#)
- [An Outside User Visits a Web Server on the DMZ, page 4-17](#)
- [An Inside User Visits a Web Server on the DMZ, page 4-19](#)
- [An Outside User Attempts to Access an Inside Host, page 4-20](#)
- [A DMZ User Attempts to Access an Inside Host, page 4-21](#)

### An Inside User Visits a Web Server

Figure 4-2 shows an inside user accessing an outside web server.

**Figure 4-2**      *Inside to Outside*

The following steps describe how data moves through the adaptive security appliance (see Figure 4-2):

1. The user on the inside network requests a web page from www.example.com.
2. The adaptive security appliance receives the packet and because it is a new session, the adaptive security appliance verifies that the packet is allowed according to the terms of the security policy (access lists, filters, AAA).

For multiple context mode, the adaptive security appliance first classifies the packet according to either a unique interface or a unique destination address associated with a context; the destination address is associated by matching an address translation in a context. In this case, the interface would be unique; the `www.example.com` IP address does not have a current address translation in a context.

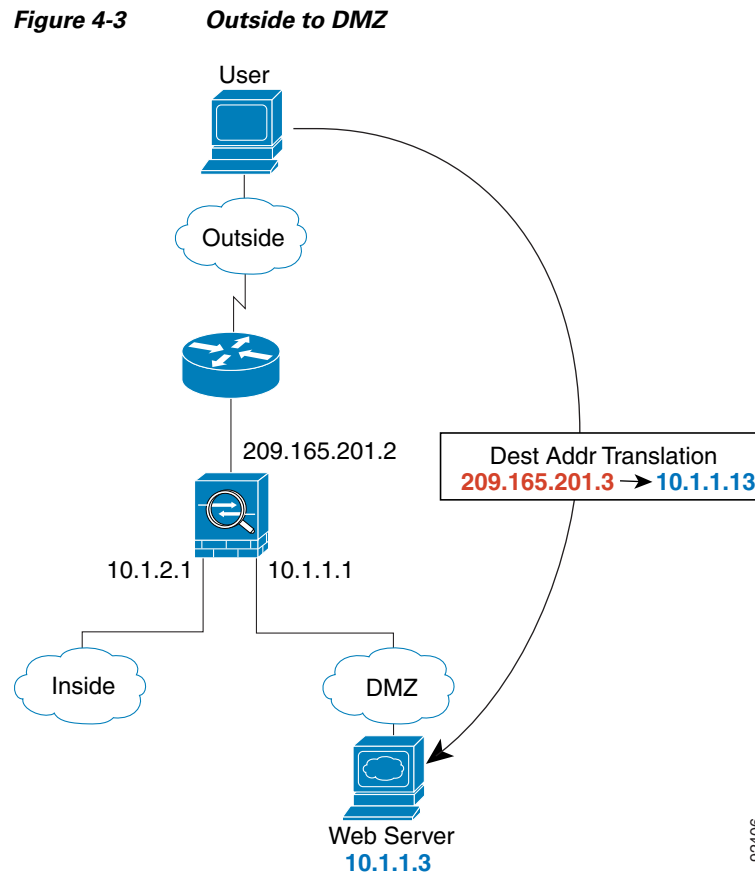

3. The adaptive security appliance translates the local source address (10.1.2.27) to the global address 209.165.201.10, which is on the outside interface subnet.

The global address could be on any subnet, but routing is simplified when it is on the outside interface subnet.

4. The adaptive security appliance then records that a session is established and forwards the packet from the outside interface.
5. When `www.example.com` responds to the request, the packet goes through the adaptive security appliance, and because the session is already established, the packet bypasses the many lookups associated with a new connection. The adaptive security appliance performs NAT by translating the global destination address to the local user address, 10.1.2.27.
6. The adaptive security appliance forwards the packet to the inside user.

## An Outside User Visits a Web Server on the DMZ

Figure 4-3 shows an outside user accessing the DMZ web server.

92406

The following steps describe how data moves through the adaptive security appliance (see [Figure 4-3](#)):

1. A user on the outside network requests a web page from the DMZ web server using the global destination address of 209.165.201.3, which is on the outside interface subnet.
2. The adaptive security appliance receives the packet and because it is a new session, the adaptive security appliance verifies that the packet is allowed according to the terms of the security policy (access lists, filters, AAA).

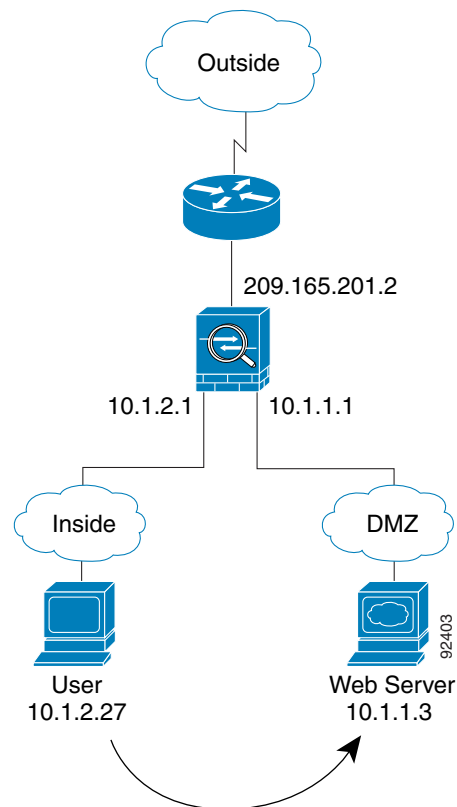

For multiple context mode, the adaptive security appliance first classifies the packet according to either a unique interface or a unique destination address associated with a context; the destination address is associated by matching an address translation in a context. In this case, the classifier “knows” that the DMZ web server address belongs to a certain context because of the server address translation.

3. The adaptive security appliance translates the destination address to the local address 10.1.1.3.
4. The adaptive security appliance then adds a session entry to the fast path and forwards the packet from the DMZ interface.
5. When the DMZ web server responds to the request, the packet goes through the adaptive security appliance and because the session is already established, the packet bypasses the many lookups associated with a new connection. The adaptive security appliance performs NAT by translating the local source address to 209.165.201.3.
6. The adaptive security appliance forwards the packet to the outside user.

## An Inside User Visits a Web Server on the DMZ

Figure 4-4 shows an inside user accessing the DMZ web server.

**Figure 4-4** *Inside to DMZ*

The following steps describe how data moves through the adaptive security appliance (see Figure 4-4):

1. A user on the inside network requests a web page from the DMZ web server using the destination address of 10.1.1.3.
2. The adaptive security appliance receives the packet and because it is a new session, the adaptive security appliance verifies that the packet is allowed according to the terms of the security policy (access lists, filters, AAA).

For multiple context mode, the adaptive security appliance first classifies the packet according to either a unique interface or a unique destination address associated with a context; the destination address is associated by matching an address translation in a context. In this case, the interface is unique; the web server IP address does not have a current address translation.

3. The adaptive security appliance then records that a session is established and forwards the packet out of the DMZ interface.
4. When the DMZ web server responds to the request, the packet goes through the fast path, which lets the packet bypass the many lookups associated with a new connection.
5. The adaptive security appliance forwards the packet to the inside user.

## An Outside User Attempts to Access an Inside Host

Figure 4-5 shows an outside user attempting to access the inside network.

**Figure 4-5** *Outside to Inside*

The following steps describe how data moves through the adaptive security appliance (see Figure 4-5):

1. A user on the outside network attempts to reach an inside host (assuming the host has a routable IP address).  
If the inside network uses private addresses, no outside user can reach the inside network without NAT. The outside user might attempt to reach an inside user by using an existing NAT session.
2. The adaptive security appliance receives the packet and because it is a new session, the adaptive security appliance verifies if the packet is allowed according to the security policy (access lists, filters, AAA).
3. The packet is denied, and the adaptive security appliance drops the packet and logs the connection attempt.

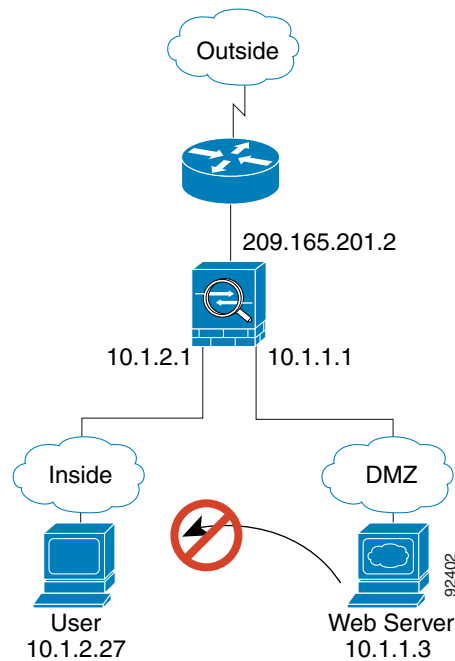

If the outside user is attempting to attack the inside network, the adaptive security appliance employs many technologies to determine if a packet is valid for an already established session.

## A DMZ User Attempts to Access an Inside Host

Figure 4-6 shows a user in the DMZ attempting to access the inside network.

**Figure 4-6** *DMZ to Inside*

The following steps describe how data moves through the adaptive security appliance (see Figure 4-6):

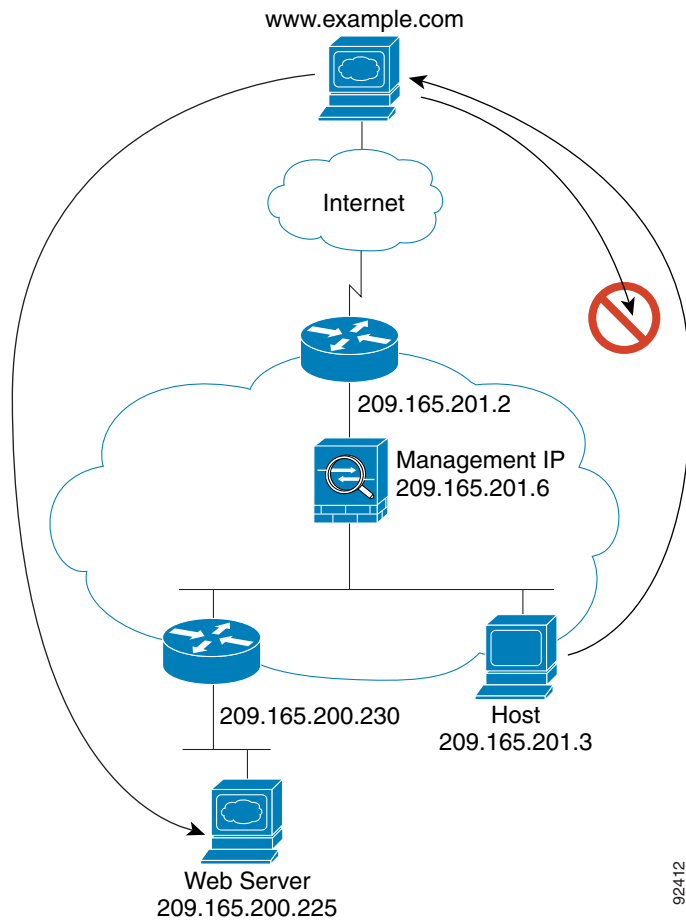

1. A user on the DMZ network attempts to reach an inside host. Because the DMZ does not have to route the traffic on the Internet, the private addressing scheme does not prevent routing.
2. The adaptive security appliance receives the packet and because it is a new session, the adaptive security appliance verifies if the packet is allowed according to the security policy (access lists, filters, AAA).

The packet is denied, and the adaptive security appliance drops the packet and logs the connection attempt.

## How Data Moves Through the Transparent Firewall

Figure 4-7 shows a typical transparent firewall implementation with an inside network that contains a public web server. The adaptive security appliance has an access list so that the inside users can access Internet resources. Another access list lets the outside users access only the web server on the inside network.

**Figure 4-7** Typical Transparent Firewall Data Path

This section describes how data moves through the adaptive security appliance and includes the following topics:

- [An Inside User Visits a Web Server, page 4-23](#)
- [An Inside User Visits a Web Server Using NAT, page 4-24](#)
- [An Outside User Visits a Web Server on the Inside Network, page 4-25](#)
- [An Outside User Attempts to Access an Inside Host, page 4-26](#)

## An Inside User Visits a Web Server

Figure 4-8 shows an inside user accessing an outside web server.

**Figure 4-8** *Inside to Outside*

The following steps describe how data moves through the adaptive security appliance (see Figure 4-8):

1. The user on the inside network requests a web page from `www.example.com`.
2. The adaptive security appliance receives the packet and adds the source MAC address to the MAC address table, if required. Because it is a new session, it verifies that the packet is allowed according to the terms of the security policy (access lists, filters, AAA).

For multiple context mode, the adaptive security appliance first classifies the packet according to a unique interface.

3. The adaptive security appliance records that a session is established.
4. If the destination MAC address is in its table, the adaptive security appliance forwards the packet out of the outside interface. The destination MAC address is that of the upstream router, 209.186.201.2.

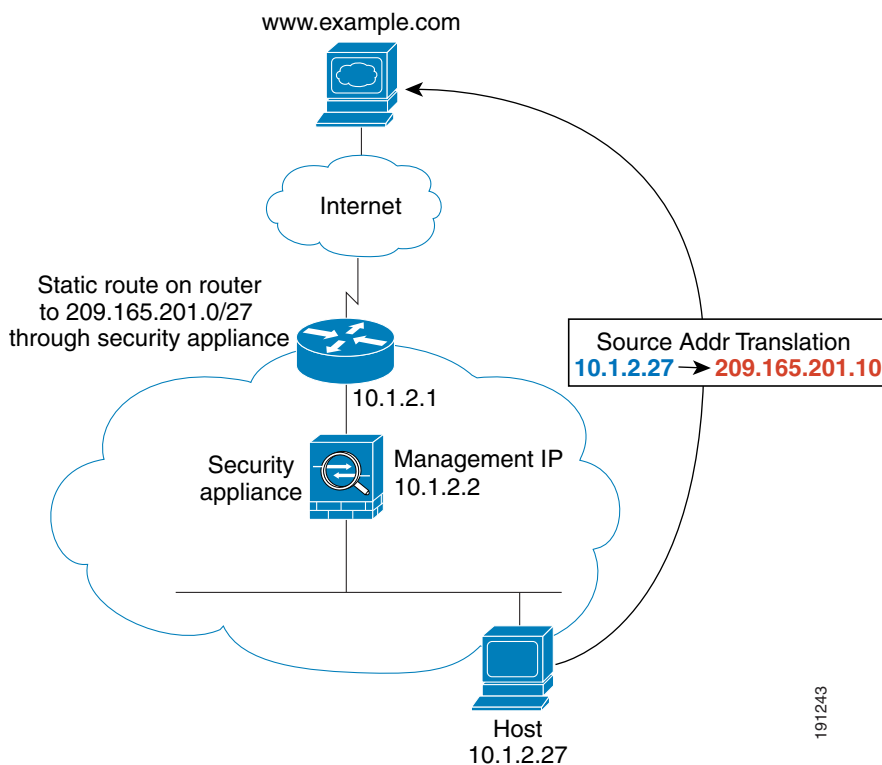

If the destination MAC address is not in the adaptive security appliance table, the adaptive security appliance attempts to discover the MAC address by sending an ARP request and a ping. The first packet is dropped.

5. The web server responds to the request; because the session is already established, the packet bypasses the many lookups associated with a new connection.
6. The adaptive security appliance forwards the packet to the inside user.

## An Inside User Visits a Web Server Using NAT

Figure 4-8 shows an inside user accessing an outside web server.

**Figure 4-9** *Inside to Outside with NAT*

The following steps describe how data moves through the adaptive security appliance (see Figure 4-8):

1. The user on the inside network requests a web page from www.example.com.
2. The adaptive security appliance receives the packet and adds the source MAC address to the MAC address table, if required. Because it is a new session, it verifies that the packet is allowed according to the terms of the security policy (access lists, filters, AAA).

For multiple context mode, the adaptive security appliance first classifies the packet according to a unique interface.

3. The adaptive security appliance translates the real address (10.1.2.27) to the mapped address 209.165.201.10.  
Because the mapped address is not on the same network as the outside interface, then be sure the upstream router has a static route to the mapped network that points to the adaptive security appliance.
4. The adaptive security appliance then records that a session is established and forwards the packet from the outside interface.
5. If the destination MAC address is in its table, the adaptive security appliance forwards the packet out of the outside interface. The destination MAC address is that of the upstream router, 10.1.2.1.

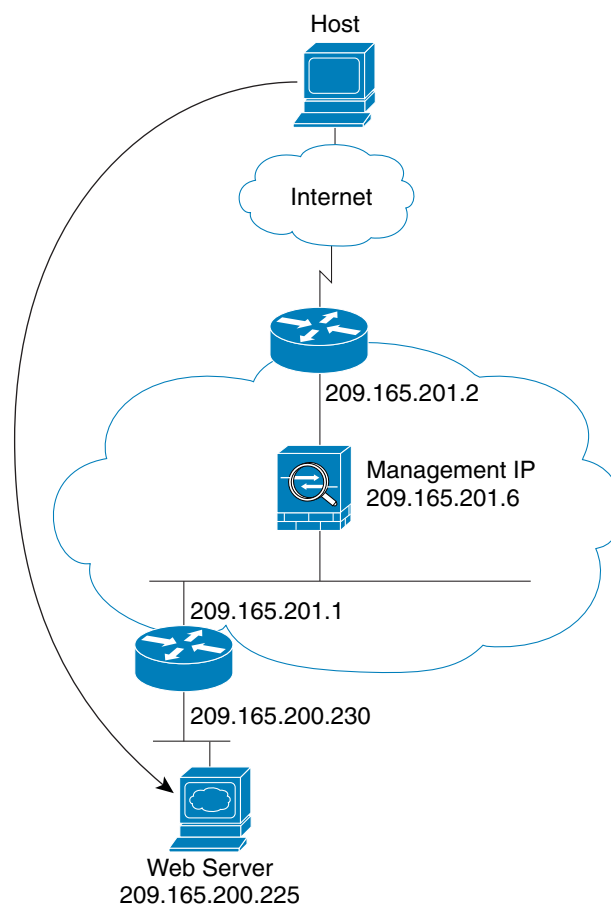

If the destination MAC address is not in the adaptive security appliance table, the adaptive security appliance attempts to discover the MAC address by sending an ARP request and a ping. The first packet is dropped.

6. The web server responds to the request; because the session is already established, the packet bypasses the many lookups associated with a new connection.
7. The adaptive security appliance performs NAT by translating the mapped address to the real address, 10.1.2.27.

## An Outside User Visits a Web Server on the Inside Network

Figure 4-10 shows an outside user accessing the inside web server.

**Figure 4-10**      *Outside to Inside*

The following steps describe how data moves through the adaptive security appliance (see Figure 4-10):

1. A user on the outside network requests a web page from the inside web server.
2. The adaptive security appliance receives the packet and adds the source MAC address to the MAC address table, if required. Because it is a new session, it verifies that the packet is allowed according to the terms of the security policy (access lists, filters, AAA).

For multiple context mode, the adaptive security appliance first classifies the packet according to a unique interface.

3. The adaptive security appliance records that a session is established.
4. If the destination MAC address is in its table, the adaptive security appliance forwards the packet out of the inside interface. The destination MAC address is that of the downstream router, 209.165.201.1.

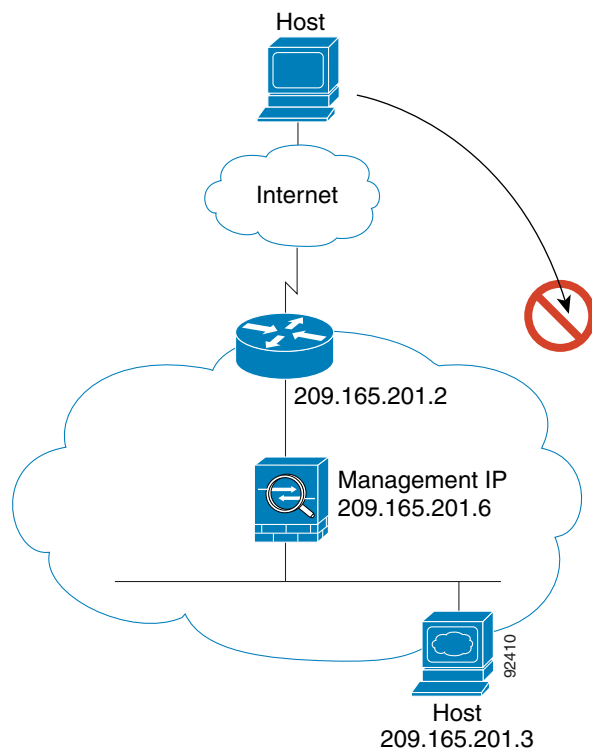

If the destination MAC address is not in the adaptive security appliance table, the adaptive security appliance attempts to discover the MAC address by sending an ARP request and a ping. The first packet is dropped.

5. The web server responds to the request; because the session is already established, the packet bypasses the many lookups associated with a new connection.
6. The adaptive security appliance forwards the packet to the outside user.

## An Outside User Attempts to Access an Inside Host

Figure 4-11 shows an outside user attempting to access a host on the inside network.

**Figure 4-11**      *Outside to Inside*

The following steps describe how data moves through the adaptive security appliance (see Figure 4-11):

1. A user on the outside network attempts to reach an inside host.
2. The adaptive security appliance receives the packet and adds the source MAC address to the MAC address table, if required. Because it is a new session, it verifies if the packet is allowed according to the terms of the security policy (access lists, filters, AAA).

For multiple context mode, the adaptive security appliance first classifies the packet according to a unique interface.

3. The packet is denied because there is no access list permitting the outside host, and the adaptive security appliance drops the packet.
4. If the outside user is attempting to attack the inside network, the adaptive security appliance employs many technologies to determine if a packet is valid for an already established session.

## **PART 2**

### **Setting up the Adaptive Security Appliance**

# CHAPTER 5

## Configuring Multiple Context Mode

---

This chapter describes how to configure multiple security contexts on the adaptive security appliance and includes the following sections:

- [Information About Security Contexts, page 5-1](#)
- [Licensing Requirements for Multiple Context Mode, page 5-12](#)
- [Guidelines and Limitations, page 5-12](#)
- [Default Settings, page 5-13](#)
- [Configuring Multiple Contexts, page 5-13](#)
- [Changing Between Contexts and the System Execution Space, page 5-23](#)
- [Managing Security Contexts, page 5-23](#)
- [Monitoring Security Contexts, page 5-27](#)
- [Configuration Examples for Multiple Context Mode, page 5-38](#)
- [Feature History for Multiple Context Mode, page 5-39](#)

## Information About Security Contexts

You can partition a single adaptive security appliance into multiple virtual devices, known as security contexts. Each context is an independent device, with its own security policy, interfaces, and administrators. Multiple contexts are similar to having multiple standalone devices. Many features are supported in multiple context mode, including routing tables, firewall features, IPS, and management. Some features are not supported, including VPN and dynamic routing protocols.

### Note

When the adaptive security appliance is configured for security contexts (for example, for Active/Active Stateful Failover), IPsec or SSL VPN cannot be enabled. Therefore, these features are unavailable.

This section provides an overview of security contexts and includes the following topics:

- [Common Uses for Security Contexts, page 5-2](#)
- [Context Configuration Files, page 5-2](#)
- [How the Security Appliance Classifies Packets, page 5-3](#)
- [Cascading Security Contexts, page 5-6](#)
- [Management Access to Security Contexts, page 5-7](#)

- [Information About Resource Management, page 5-8](#)
- [Information About MAC Addresses, page 5-11](#)

## Common Uses for Security Contexts

You might want to use multiple security contexts in the following situations:

- You are a service provider and want to sell security services to many customers. By enabling multiple security contexts on the adaptive security appliance, you can implement a cost-effective, space-saving solution that keeps all customer traffic separate and secure, and also eases configuration.
- You are a large enterprise or a college campus and want to keep departments completely separate.
- You are an enterprise that wants to provide distinct security policies to different departments.
- You have any network that requires more than one adaptive security appliance.

## Context Configuration Files

This section describes how the adaptive security appliance implements multiple context mode configurations and includes the following sections:

- [Context Configurations, page 5-2](#)
- [System Configuration, page 5-2](#)
- [Admin Context Configuration, page 5-2](#)

### Context Configurations

The adaptive security appliance includes a configuration for each context that identifies the security policy, interfaces, and almost all the options you can configure on a standalone device. You can store context configurations on the internal flash memory or the external flash memory card, or you can download them from a TFTP, FTP, or HTTP(S) server.

### System Configuration

The system administrator adds and manages contexts by configuring each context configuration location, allocated interfaces, and other context operating parameters in the system configuration, which, like a single mode configuration, is the startup configuration. The system configuration identifies basic settings for the adaptive security appliance. The system configuration does not include any network interfaces or network settings for itself; rather, when the system needs to access network resources (such as downloading the contexts from the server), it uses one of the contexts that is designated as the *admin context*. The system configuration does include a specialized failover interface for failover traffic only.

### Admin Context Configuration

The admin context is just like any other context, except that when a user logs in to the admin context, then that user has system administrator rights and can access the system and all other contexts. The admin context is not restricted in any way, and can be used as a regular context. However, because

logging into the admin context grants you administrator privileges over all contexts, you might need to restrict access to the admin context to appropriate users. The admin context must reside on flash memory, and not remotely.

If your system is already in multiple context mode, or if you convert from single mode, the admin context is created automatically as a file on the internal flash memory called `admin.cfg`. This context is named “admin.” If you do not want to use `admin.cfg` as the admin context, you can change the admin context.

## How the Security Appliance Classifies Packets

Each packet that enters the adaptive security appliance must be classified, so that the adaptive security appliance can determine to which context to send a packet. This section includes the following topics:

- [Valid Classifier Criteria, page 5-3](#)
- [Classification Examples, page 5-4](#)

**Note**

If the destination MAC address is a multicast or broadcast MAC address, the packet is duplicated and delivered to each context.

### Valid Classifier Criteria

This section describes the criteria used by the classifier and includes the following topics:

- [Unique Interfaces, page 5-3](#)
- [Unique MAC Addresses, page 5-3](#)
- [NAT Configuration, page 5-4](#)

**Note**

For management traffic destined for an interface, the interface IP address is used for classification.

The routing table is not used for packet classification.

### Unique Interfaces

If only one context is associated with the ingress interface, the adaptive security appliance classifies the packet into that context. In transparent firewall mode, unique interfaces for contexts are required, so this method is used to classify packets at all times.

### Unique MAC Addresses

If multiple contexts share an interface, then the classifier uses the interface MAC address. The adaptive security appliance lets you assign a different MAC address in each context to the same shared interface, whether it is a shared physical interface or a shared subinterface. By default, shared interfaces do not have unique MAC addresses; the interface uses the physical interface burned-in MAC address in every context. An upstream router cannot route directly to a context without unique MAC addresses. You can set the MAC addresses manually when you configure each interface (see the [“Configuring the MAC Address” section on page 6-26](#)), or you can automatically generate MAC addresses (see the [“Automatically Assigning MAC Addresses to Context Interfaces” section on page 5-22](#)).

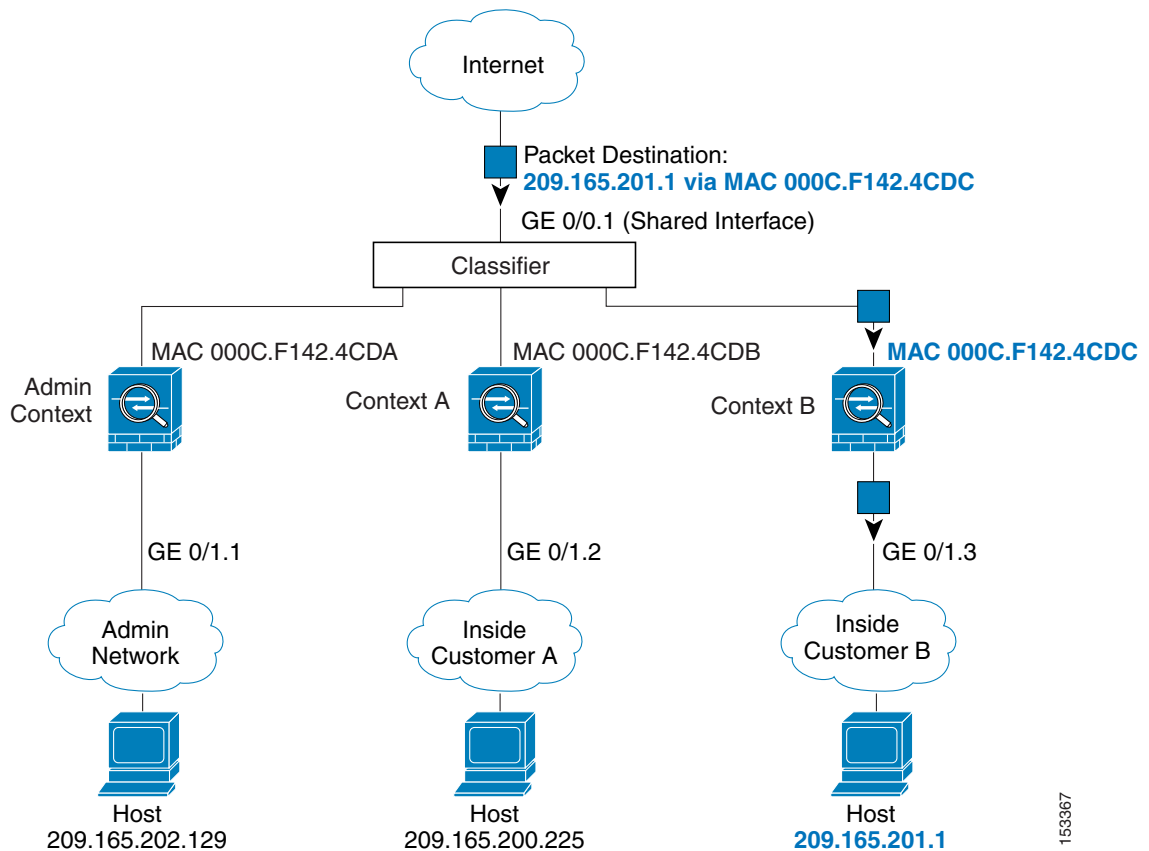

## NAT Configuration

If you do not use unique MAC addresses, then the mapped addresses in your NAT configuration are used to classify packets. We recommend using MAC addresses instead of NAT, so that traffic classification can occur regardless of the completeness of the NAT configuration.

## Classification Examples

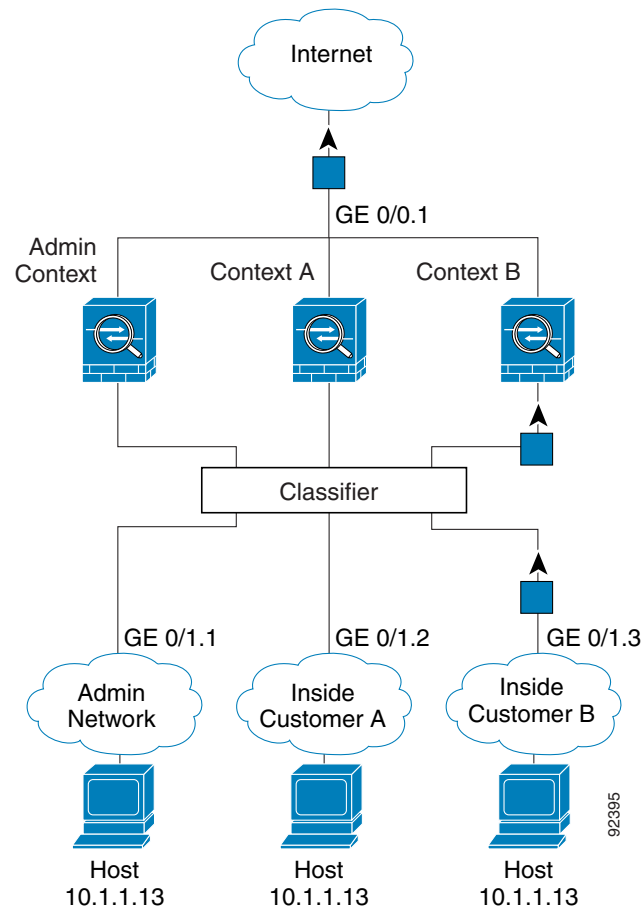

Figure 5-1 shows multiple contexts sharing an outside interface. The classifier assigns the packet to Context B because Context B includes the MAC address to which the router sends the packet.

**Figure 5-1** Packet Classification with a Shared Interface using MAC Addresses

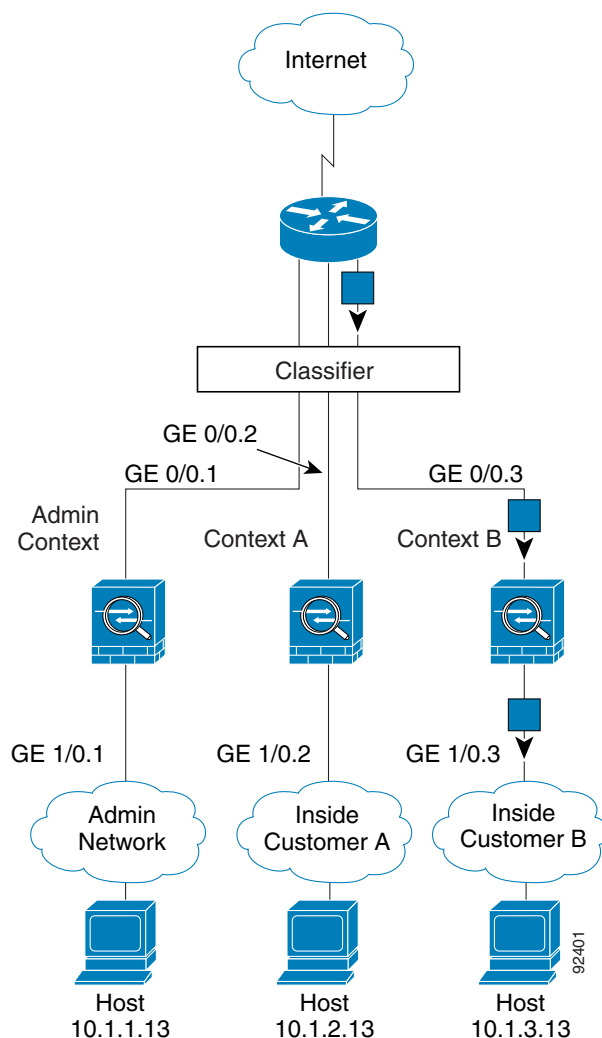

Note that all new incoming traffic must be classified, even from inside networks. [Figure 5-2](#) shows a host on the Context B inside network accessing the Internet. The classifier assigns the packet to Context B because the ingress interface is Gigabit Ethernet 0/1.3, which is assigned to Context B.

**Figure 5-2** Incoming Traffic from Inside Networks

For transparent firewalls, you must use unique interfaces. [Figure 5-3](#) shows a host on the Context B inside network accessing the Internet. The classifier assigns the packet to Context B because the ingress interface is Gigabit Ethernet 1/0.3, which is assigned to Context B.

**Figure 5-3** Transparent Firewall Contexts

## Cascading Security Contexts

Placing a context directly in front of another context is called cascading contexts; the outside interface of one context is the same interface as the inside interface of another context. You might want to cascade contexts if you want to simplify the configuration of some contexts by configuring shared parameters in the top context.

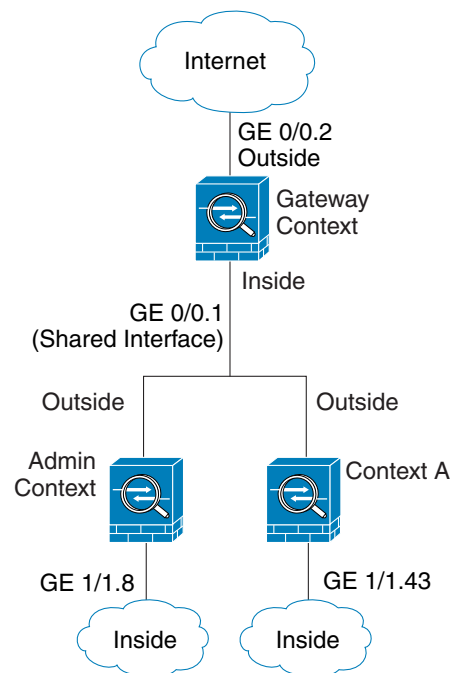

### Note

Cascading contexts requires that you configure unique MAC addresses for each context interface. Because of the limitations of classifying packets on shared interfaces without MAC addresses, we do not recommend using cascading contexts without unique MAC addresses.

Figure 5-4 shows a gateway context with two contexts behind the gateway.

**Figure 5-4 Cascading Contexts**

## Management Access to Security Contexts

The adaptive security appliance provides system administrator access in multiple context mode as well as access for individual context administrators. The following sections describe logging in as a system administrator or as a context administrator:

- [System Administrator Access, page 5-7](#)
- [Context Administrator Access, page 5-8](#)

### System Administrator Access

You can access the adaptive security appliance as a system administrator in two ways:

- Access the adaptive security appliance console.  
From the console, you access the *system execution space*, which means that any commands you enter affect only the system configuration or the running of the system (for run-time commands).
- Access the admin context using Telnet, SSH, or ASDM.

See [Chapter 34, “Configuring Management Access,”](#) to enable Telnet, SSH, and SDM access.

As the system administrator, you can access all contexts.

When you change to a context from admin or the system, your username changes to the default “enable\_15” username. If you configured command authorization in that context, you need to either configure authorization privileges for the “enable\_15” user, or you can log in as a different name for which you provide sufficient privileges in the command authorization configuration for the context. To

log in with a username, enter the **login** command. For example, you log in to the admin context with the username “admin.” The admin context does not have any command authorization configuration, but all other contexts include command authorization. For convenience, each context configuration includes a user “admin” with maximum privileges. When you change from the admin context to context A, your username is altered, so you must log in again as “admin” by entering the **login** command. When you change to context B, you must again enter the **login** command to log in as “admin.”

The system execution space does not support any AAA commands, but you can configure its own enable password, as well as usernames in the local database to provide individual logins.

## Context Administrator Access

You can access a context using Telnet, SSH, or ASDM. If you log in to a non-admin context, you can only access the configuration for that context. You can provide individual logins to the context. See [Chapter 34, “Configuring Management Access,”](#) to enable Telnet, SSH, and SDM access and to configure management authentication.

## Information About Resource Management

By default, all security contexts have unlimited access to the resources of the adaptive security appliance, except where maximum limits per context are enforced. However, if you find that one or more contexts use too many resources, and they cause other contexts to be denied connections, for example, then you can configure resource management to limit the use of resources per context.

The adaptive security appliance manages resources by assigning contexts to resource classes. Each context uses the resource limits set by the class.

This section includes the following topics:

- [Resource Limits, page 5-8](#)
- [Default Class, page 5-9](#)
- [Class Members, page 5-10](#)

## Resource Limits

When you create a class, the adaptive security appliance does not set aside a portion of the resources for each context assigned to the class; rather, the adaptive security appliance sets the maximum limit for a context. If you oversubscribe resources, or allow some resources to be unlimited, a few contexts can “use up” those resources, potentially affecting service to other contexts.

You can set the limit for individual resources, as a percentage (if there is a hard system limit) or as an absolute value.

You can oversubscribe the adaptive security appliance by assigning more than 100 percent of a resource across all contexts. For example, you can set the Bronze class to limit connections to 20 percent per context, and then assign 10 contexts to the class for a total of 200 percent. If contexts concurrently use more than the system limit, then each context gets less than the 20 percent you intended. (See [Figure 5-5.](#))

**Figure 5-5 Resource Oversubscription**

If you assign an absolute value to a resource across all contexts that exceeds the practical limit of the adaptive security appliance, then the performance of the adaptive security appliance might be impaired.

The adaptive security appliance lets you assign unlimited access to one or more resources in a class, instead of a percentage or absolute number. When a resource is unlimited, contexts can use as much of the resource as the system has available or that is practically available. For example, Context A, B, and C are in the Silver Class, which limits each class member to 1 percent of the connections, for a total of 3 percent; but the three contexts are currently only using 2 percent combined. Gold Class has unlimited access to connections. The contexts in the Gold Class can use more than the 97 percent of “unassigned” connections; they can also use the 1 percent of connections not currently in use by Context A, B, and C, even if that means that Context A, B, and C are unable to reach their 3 percent combined limit. (See [Figure 5-6](#).) Setting unlimited access is similar to oversubscribing the adaptive security appliance, except that you have less control over how much you oversubscribe the system.

**Figure 5-6 Unlimited Resources**

## Default Class

All contexts belong to the default class if they are not assigned to another class; you do not have to actively assign a context to the default class.

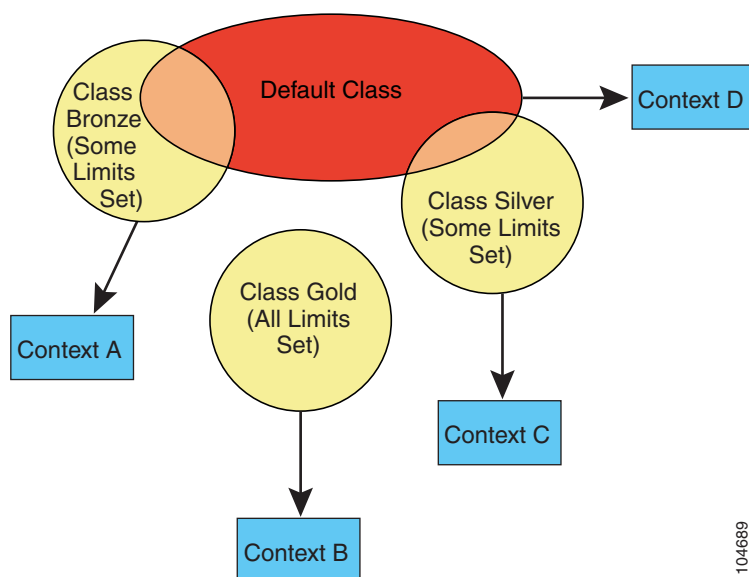

If a context belongs to a class other than the default class, those class settings always override the default class settings. However, if the other class has any settings that are not defined, then the member context uses the default class for those limits. For example, if you create a class with a 2 percent limit for all concurrent connections, but no other limits, then all other limits are inherited from the default class. Conversely, if you create a class with a limit for all resources, the class uses no settings from the default class.

By default, the default class provides unlimited access to resources for all contexts, except for the following limits, which are by default set to the maximum allowed per context:

- Telnet sessions—5 sessions.
- SSH sessions—5 sessions.
- IPsec sessions—5 sessions.
- MAC addresses—65,535 entries.

Figure 5-7 shows the relationship between the default class and other classes. Contexts A and C belong to classes with some limits set; other limits are inherited from the default class. Context B inherits no limits from default because all limits are set in its class, the Gold class. Context D was not assigned to a class, and is by default a member of the default class.

**Figure 5-7 Resource Classes**

104689

## Class Members

To use the settings of a class, assign the context to the class when you define the context. All contexts belong to the default class if they are not assigned to another class; you do not have to actively assign a context to default. You can only assign a context to one resource class. The exception to this rule is that limits that are undefined in the member class are inherited from the default class; so in effect, a context could be a member of default plus another class.

## Information About MAC Addresses

To allow contexts to share interfaces, we suggest that you assign unique MAC addresses to each shared context interface (see the [“Automatically Assigning MAC Addresses to Context Interfaces”](#) section on page 5-22).

The MAC address is used to classify packets within a context. If you share an interface, but do not have unique MAC addresses for the interface in each context, then the destination IP address is used to classify packets. The destination address is matched with the context NAT configuration, and this method has some limitations compared to the MAC address method. See the [“How the Security Appliance Classifies Packets”](#) section on page 5-3 for information about classifying packets.

In the rare circumstance that the generated MAC address conflicts with another private MAC address in your network, you can manually set the MAC address for the interface within the context. See the [“Configuring the MAC Address”](#) section on page 6-26 to manually set the MAC address.

This section includes the following topics:

- [Default MAC Address, page 5-11](#)
- [Interaction with Manual MAC Addresses, page 5-11](#)
- [Failover MAC Addresses, page 5-11](#)
- [MAC Address Format, page 5-11](#)

### Default MAC Address

By default, the physical interface uses the burned-in MAC address, and all subinterfaces of a physical interface use the same burned-in MAC address.

All auto-generated MAC addresses start with A2. The auto-generated MAC addresses are persistent across reloads.

### Interaction with Manual MAC Addresses

If you manually assign a MAC address and also enable auto-generation, then the manually assigned MAC address is used. If you later remove the manual MAC address, the auto-generated address is used.

Because auto-generated addresses start with A2, you cannot start manual MAC addresses with A2 if you also want to use auto-generation.

### Failover MAC Addresses

For use with failover, the adaptive security appliance generates both an active and standby MAC address for each interface. If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption. See the [“MAC Address Format”](#) section for more information.

For upgrading failover units with the legacy version of the **mac-address auto** command before the **prefix** keyword was introduced, see the **mac-address auto** command in the *Cisco ASA 5500 Series Command Reference*.

### MAC Address Format

The adaptive security appliance generates the MAC address using the following format:

A2xx.yyyz.zzzz

Where xx.yy is a user-defined prefix, and zz.zzzz is an internal counter generated by the adaptive security appliance. For the standby MAC address, the address is identical except that the internal counter is increased by 1.

For an example of how the prefix is used, if you set a prefix of 77, then the adaptive security appliance converts 77 into the hexadecimal value 004D (yyxx). When used in the MAC address, the prefix is reversed (xxyy) to match the adaptive security appliance native form:

A24D.00zz.zzzz

For a prefix of 1009 (03F1), the MAC address is:

A2F1.03zz.zzzz

## Licensing Requirements for Multiple Context Mode

| Model                | License Requirement                                                               |
|----------------------|-----------------------------------------------------------------------------------|
| ASA 5505             | No support.                                                                       |
| ASA 5510             | Security Plus License: 2 contexts.<br><i>Optional license: 5 contexts.</i>        |
| ASA 5520             | Base License: 2 contexts.<br><i>Optional licenses: 5, 10, or 20 contexts.</i>     |
| ASA 5540, 5550, 5580 | Base License: 2 contexts.<br><i>Optional licenses: 5, 10, 20, or 50 contexts.</i> |

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

### Failover Guidelines

Active/Active mode failover is only supported in multiple context mode.

### IPv6 Guidelines

Supports IPv6.

### Model Guidelines

Does not support the ASA 5505.

### Unsupported Features

Multiple context mode does not support the following features:

- Dynamic routing protocols  
Security contexts support only static routes. You cannot enable OSPF, RIP, or EIGRP in multiple context mode.
- VPN
- Multicast routing. Multicast bridging is supported.
- Threat Detection
- Phone Proxy
- QoS

**Additional Guidelines**

The context mode (single or multiple) is not stored in the configuration file, even though it does endure reboots. If you need to copy your configuration to another device, set the mode on the new device to match.

## Default Settings

By default, the adaptive security appliance is in single context mode.

## Configuring Multiple Contexts

This section describes how to configure multiple context mode, and includes the following topics:

- [Task Flow for Configuring Multiple Context Mode, page 5-13](#)
- [Enabling or Disabling Multiple Context Mode, page 5-14](#)
- [Configuring a Class for Resource Management, page 5-15](#)
- [Configuring a Security Context, page 5-17](#)
- [Automatically Assigning MAC Addresses to Context Interfaces, page 5-22](#)

## Task Flow for Configuring Multiple Context Mode

To configure multiple context mode, perform the following steps:

- 
- |               |                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Enable multiple context mode. See the <a href="#">“Enabling or Disabling Multiple Context Mode”</a> section on <a href="#">page 5-14</a> .                                                        |
| <b>Step 2</b> | (Optional) Configure classes for resource management. See the <a href="#">“Configuring a Class for Resource Management”</a> section on <a href="#">page 5-15</a> .                                |
| <b>Step 3</b> | Configure security contexts. See the <a href="#">“Configuring a Security Context”</a> section on <a href="#">page 5-17</a> .                                                                      |
| <b>Step 4</b> | (Optional) Automatically assign MAC addresses to context interfaces. See the <a href="#">“Automatically Assigning MAC Addresses to Context Interfaces”</a> section on <a href="#">page 5-22</a> . |
-

## Enabling or Disabling Multiple Context Mode

Your adaptive security appliance might already be configured for multiple security contexts depending on how you ordered it from Cisco. If you are upgrading, however, you might need to convert from single mode to multiple mode by following the procedures in this section.

This section includes the following topics:

- [Enabling Multiple Context Mode, page 5-14](#)
- [Restoring Single Context Mode, page 5-14](#)

### Enabling Multiple Context Mode

When you convert from single mode to multiple mode, the adaptive security appliance converts the running configuration into two files: a new startup configuration that comprises the system configuration, and admin.cfg that comprises the admin context (in the root directory of the internal flash memory). The original running configuration is saved as old\_running.cfg (in the root directory of the internal flash memory). The original startup configuration is not saved. The adaptive security appliance automatically adds an entry for the admin context to the system configuration with the name “admin.”

#### Prerequisites

- When you convert from single mode to multiple mode, the adaptive security appliance converts the running configuration into two files. The original startup configuration is not saved, so if it differs from the running configuration, you should back it up before proceeding.
- The context mode (single or multiple) is not stored in the configuration file, even though it does endure reboots. If you need to copy your configuration to another device, set the mode on the new device to match.

#### Detailed Steps

| Command                                            | Purpose                                                                                       |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------|
| <b>mode multiple</b>                               | Changes to multiple context mode. You are prompted to reboot the adaptive security appliance. |
| <b>Example:</b><br>hostname(config)# mode multiple |                                                                                               |

### Restoring Single Context Mode

To copy the old running configuration to the startup configuration and to change the mode to single mode, perform the following steps.

#### Prerequisites

Perform this procedure in the system execution space.

## Detailed Steps

|        | Command                                                                                                                                           | Purpose                                                                                                |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| Step 1 | <b>copy flash:old_running.cfg startup-config</b><br><br><b>Example:</b><br><pre>hostname(config)# copy flash:old_running.cfg startup-config</pre> | Copies the backup version of your original running configuration to the current startup configuration. |
| Step 2 | <b>mode single</b><br><br><b>Example:</b><br><pre>hostname(config)# mode single</pre>                                                             | Sets the mode to single mode. You are prompted to reboot the adaptive security appliance.              |

## Configuring a Class for Resource Management

To configure a class in the system configuration, perform the following steps. You can change the value of a particular resource limit by reentering the command with a new value.

### Prerequisites

Perform this procedure in the system execution space.

### Guidelines

[Table 5-1](#) lists the resource types and the limits. See also the **show resource types** command.

**Table 5-1** Resource Names and Limits

| Resource Name | Rate or Concurrent | Minimum and Maximum Number per Context | System Limit <sup>1</sup>                                                                                                                                                           | Description                                                                                                    |
|---------------|--------------------|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| mac-addresses | Concurrent         | N/A                                    | 65,535                                                                                                                                                                              | For transparent firewall mode, the number of MAC addresses allowed in the MAC address table.                   |
| conns         | Concurrent or Rate | N/A                                    | Concurrent connections: See the <a href="#">“Supported Feature Licenses Per Model”</a> section on <a href="#">page 3-1</a> for the connection limit for your platform.<br>Rate: N/A | TCP or UDP connections between any two hosts, including connections between one host and multiple other hosts. |
| inspects      | Rate               | N/A                                    | N/A                                                                                                                                                                                 | Application inspections.                                                                                       |
| hosts         | Concurrent         | N/A                                    | N/A                                                                                                                                                                                 | Hosts that can connect through the adaptive security appliance.                                                |

Table 5-1 Resource Names and Limits (continued)

| Resource Name | Rate or Concurrent | Minimum and Maximum Number per Context | System Limit <sup>1</sup> | Description                                                                                                                                                                                                                                                                                                      |
|---------------|--------------------|----------------------------------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| asdm          | Concurrent         | 1 minimum<br>5 maximum                 | 32                        | ASDM management sessions.<br><br><b>Note</b> ASDM sessions use two HTTPS connections: one for monitoring that is always present, and one for making configuration changes that is present only when you make changes. For example, the system limit of 32 ASDM sessions represents a limit of 64 HTTPS sessions. |
| ssh           | Concurrent         | 1 minimum<br>5 maximum                 | 100                       | SSH sessions.                                                                                                                                                                                                                                                                                                    |
| syslogs       | Rate               | N/A                                    | N/A                       | System log messages.                                                                                                                                                                                                                                                                                             |
| telnet        | Concurrent         | 1 minimum<br>5 maximum                 | 100                       | Telnet sessions.                                                                                                                                                                                                                                                                                                 |
| xlates        | Concurrent         | N/A                                    | N/A                       | Address translations.                                                                                                                                                                                                                                                                                            |

1. If this column value is N/A, then you cannot set a percentage of the resource because there is no hard system limit for the resource.

## Detailed Steps

|               | Command                                                                                                                                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>class</b> <i>name</i><br><br><b>Example:</b><br><pre>hostname(config)# threat-detection scanning-threat shun except ip-address 10.1.1.0 255.255.255.0</pre>                                                                                                                                 | Specifies the class name and enters the class configuration mode. The <i>name</i> is a string up to 20 characters long. To set the limits for the default class, enter <b>default</b> for the name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 2</b> | Do one or more of the following:<br><br><b>limit-resource all 0</b><br><br><b>Example:</b><br><pre>hostname(config)# limit-resource all 0</pre><br><b>limit-resource [rate] resource_name number[%]</b><br><br><b>Example:</b><br><pre>hostname(config)# limit-resource rate inspects 10</pre> | Sets all resource limits (shown in <a href="#">Table 5-1</a> ) to be unlimited. For example, you might want to create a class that includes the admin context that has no limitations. The default class has all resources set to unlimited by default.<br><br>Sets a particular resource limit. For this particular resource, the limit overrides the limit set for <b>all</b> . Enter the <b>rate</b> argument to set the rate per second for certain resources. For resources that do not have a system limit, you cannot set the percentage (%) between 1 and 100; you can only set an absolute value. See <a href="#">Table 5-1</a> for resources for which you can set the rate per second and which do not have a system limit. |

## Examples

For example, to set the default class limit for conns to 10 percent instead of unlimited, enter the following commands:

```
hostname(config)# class default
hostname(config-class)# limit-resource conns 10%
```

All other resources remain at unlimited.

To add a class called gold, enter the following commands:

```
hostname(config)# class gold
hostname(config-class)# limit-resource mac-addresses 10000
hostname(config-class)# limit-resource conns 15%
hostname(config-class)# limit-resource rate conns 1000
hostname(config-class)# limit-resource rate inspects 500
hostname(config-class)# limit-resource hosts 9000
hostname(config-class)# limit-resource asdm 5
hostname(config-class)# limit-resource ssh 5
hostname(config-class)# limit-resource rate syslogs 5000
hostname(config-class)# limit-resource telnet 5
hostname(config-class)# limit-resource xlates 36000
```

## Configuring a Security Context

The security context definition in the system configuration identifies the context name, configuration file URL, and interfaces that a context can use.

### Prerequisites

- Perform this procedure in the system execution space.
- Configure physical interface parameters, VLAN subinterfaces, and redundant interfaces according to the [“Starting Interface Configuration \(ASA 5510 and Higher\)”](#) section on page 6-8.
- If you do not have an admin context (for example, if you clear the configuration) then you must first specify the admin context name by entering the following command:

```
hostname(config)# admin-context name
```

Although this context name does not exist yet in your configuration, you can subsequently enter the **context** *name* command to match the specified name to continue the admin context configuration.

### Detailed Steps

|        | Command                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p><b>context</b> <i>name</i></p> <p><b>Example:</b><br/> hostname(config)# context administrator</p>                                        | <p>Adds or modifies a context. The <i>name</i> is a string up to 32 characters long. This name is case sensitive, so you can have two contexts named “customerA” and “CustomerA,” for example. You can use letters, digits, or hyphens, but you cannot start or end the name with a hyphen.</p> <p>“System” or “Null” (in upper or lower case letters) are reserved names, and cannot be used.</p> |
| Step 2 | <p>(Optional)</p> <p><b>description</b> <i>text</i></p> <p><b>Example:</b><br/> hostname(config)# description<br/> Administrator Context</p> | <p>Adds a description for this context.</p>                                                                                                                                                                                                                                                                                                                                                        |

|        | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <p>To allocate a physical interface:</p> <pre><b>allocate-interface</b> <i>physical_interface</i> [<i>mapped_name</i>] [<b>visible</b>   <b>invisible</b>]</pre> <p>To allocate one or more subinterfaces:</p> <pre><b>allocate-interface</b> <i>physical_interface.subinterface</i>[-<i>physical_interface.subinterface</i>] [<i>mapped_name</i>[-<i>mapped_name</i>]] [<b>visible</b>   <b>invisible</b>]</pre> <p><b>Example:</b></p> <pre>hostname(config-ctx)# allocate-interface gigabitethernet0/1.100 int1 hostname(config-ctx)# allocate-interface gigabitethernet0/1.200 int2 hostname(config-ctx)# allocate-interface gigabitethernet0/2.300-gigabitethernet0/2.305 int3-int8</pre> | <p>Specifies the interfaces you can use in the context. Do not include a space between the interface type and the port number.</p> <p>Enter these commands multiple times to specify different ranges. If you remove an allocation with the <b>no</b> form of this command, then any context commands that include this interface are removed from the running configuration.</p> <p>Transparent firewall mode allows only two interfaces to pass through traffic; however, you can use the dedicated management interface, Management 0/0 or 1/0, (either the physical interface or a subinterface) as a third interface for management traffic.</p> <p><b>Note</b> The management interface for transparent mode does not flood a packet out the interface when that packet is not in the MAC address table.</p> <p>You can assign the same interfaces to multiple contexts in routed mode, if desired. Transparent mode does not allow shared interfaces.</p> <p>The <i>mapped_name</i> is an alphanumeric alias for the interface that can be used within the context instead of the interface ID. If you do not specify a mapped name, the interface ID is used within the context. For security purposes, you might not want the context administrator to know which interfaces are being used by the context.</p> <p>A mapped name must start with a letter, end with a letter or digit, and have as interior characters only letters, digits, or an underscore. For example, you can use the following names:</p> <pre>int0, inta, int_0</pre> <p>If you specify a range of subinterfaces, you can specify a matching range of mapped names. Follow these guidelines for ranges:</p> <ul style="list-style-type: none"> <li>The mapped name must consist of an alphabetic portion followed by a numeric portion. The alphabetic portion of the mapped name must match for both ends of the range. For example, enter the following range: <pre>int0-int10</pre> <p>If you enter <b>gigabitethernet0/1.1-gigabitethernet0/1.5 happy1-sad5</b>, for example, the command fails.</p> </li> <li>The numeric portion of the mapped name must include the same quantity of numbers as the subinterface range. For example, both ranges include 100 interfaces: <pre>gigabitethernet0/0.100-gigabitethernet0/0.199 int1-int100</pre> <p>If you enter <b>gigabitethernet0/0.100-gigabitethernet0/0.199 int1-int15</b>, for example, the command fails.</p> </li> </ul> <p>Specify <b>visible</b> to see physical interface properties in the <b>show interface</b> command even if you set a mapped name. The default <b>invisible</b> keyword specifies to only show the mapped name.</p> |

| Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>Step 3</b> To allocate a physical interface:</p> <pre>allocate-interface physical_interface [mapped_name] [visible   invisible]</pre> <p>To allocate one or more subinterfaces:</p> <pre>allocate-interface physical_interface.subinterface[-physical_ interface.subinterface] [mapped_name[-mapped_name]] [visible   invisible]</pre> <p><b>Example:</b></p> <pre>hostname(config-ctx)# allocate-interface gigabitethernet0/1.100 int1 hostname(config-ctx)# allocate-interface gigabitethernet0/1.200 int2 hostname(config-ctx)# allocate-interface gigabitethernet0/2.300-gigabitethernet0/2. 305 int3-int8</pre> | <p>Specifies the interfaces you can use in the context. Do not include a space between the interface type and the port number.</p> <p>Enter these commands multiple times to specify different ranges. If you remove an allocation with the <b>no</b> form of this command, then any context commands that include this interface are removed from the running configuration.</p> <p>Transparent firewall mode allows only two interfaces to pass through traffic; however, you can use the dedicated management interface, Management 0/0 or 1/0, (either the physical interface or a subinterface) as a third interface for management traffic.</p> <p><b>Note</b> The management interface for transparent mode does not flood a packet out the interface when that packet is not in the MAC address table.</p> <p>You can assign the same interfaces to multiple contexts in routed mode, if desired. Transparent mode does not allow shared interfaces.</p> <p>The <i>mapped_name</i> is an alphanumeric alias for the interface that can be used within the context instead of the interface ID. If you do not specify a mapped name, the interface ID is used within the context. For security purposes, you might not want the context administrator to know which interfaces are being used by the context.</p> <p>A mapped name must start with a letter, end with a letter or digit, and have as interior characters only letters, digits, or an underscore. For example, you can use the following names:</p> <pre>int0, inta, int_0</pre> <p>If you specify a range of subinterfaces, you can specify a matching range of mapped names. Follow these guidelines for ranges:</p> <ul style="list-style-type: none"> <li>The mapped name must consist of an alphabetic portion followed by a numeric portion. The alphabetic portion of the mapped name must match for both ends of the range. For example, enter the following range: <pre>int0-int10</pre> <p>If you enter <b>gigabitethernet0/1.1-gigabitethernet0/1.5 happy1-sad5</b>, for example, the command fails.</p></li> <li>The numeric portion of the mapped name must include the same quantity of numbers as the subinterface range. For example, both ranges include 100 interfaces: <pre>gigabitethernet0/0.100-gigabitethernet0/0.199 int1-int100</pre> <p>If you enter <b>gigabitethernet0/0.100-gigabitethernet0/0.199 int1-int15</b>, for example, the command fails.</p></li> </ul> <p>Specify <b>visible</b> to see physical interface properties in the <b>show interface</b> command even if you set a mapped name. The default <b>invisible</b> keyword specifies to only show the mapped name.</p> |

|        | Command                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <p><b>config-url</b> <i>url</i></p> <p><b>Example:</b></p> <pre>hostname(config-ctx)# config-url ftp://user1:passw0rd@10.1.1.1/configlets/test.cfg</pre> | <p>Identifies the URL from which the system downloads the context configuration. When you add a context URL, the system immediately loads the context so that it is running, if the configuration is available.</p> <p><b>Note</b> Enter the <b>allocate-interface</b> command(s) before you enter the <b>config-url</b> command. If you enter the <b>config-url</b> command first, the adaptive security appliance loads the context configuration immediately. If the context contains any commands that refer to (not yet configured) interfaces, those commands fail.</p> <p>The filename does not require a file extension, although we recommend using “.cfg”. The server must be accessible from the admin context. If the configuration file is not available, you see the following message:</p> <pre>WARNING: Could not fetch the URL disk:/url INFO: Creating context with default config</pre> <p>For non-HTTP(S) URL locations, after you specify the URL, you can then change to the context, configure it at the CLI, and enter the <b>write memory</b> command to write the file to the URL location. (HTTP(S) is read only).</p> <p><b>Note</b> The admin context file must be stored on the internal flash memory.</p> <p>See the following URL syntax:</p> <ul style="list-style-type: none"> <li>• <b>disk:</b><i>/[path]/filename</i><br/>This URL indicates the internal flash memory.</li> <li>• <b>ftp:</b><i>//[user[:password]]@[server[:port]]/[path]/filename[:type=xx]</i><br/>The <b>type</b> can be one of the following keywords: <ul style="list-style-type: none"> <li>– <b>ap</b>—ASCII passive mode</li> <li>– <b>an</b>—ASCII normal mode</li> <li>– <b>ip</b>—(Default) Binary passive mode</li> <li>– <b>in</b>—Binary normal mode</li> </ul> </li> <li>• <b>http[s]:</b><i>//[user[:password]]@[server[:port]]/[path]/filename</i><br/>If you change to the context and configure the context at the CLI, you cannot save changes back to HTTP or HTTPS servers using the <b>write memory</b> command. You can, however, use the <b>copy tftp</b> command to copy the running configuration to a TFTP server.</li> <li>• <b>tftp:</b><i>//[user[:password]]@[server[:port]]/[path]/filename[:int=interface_name]</i></li> </ul> <p>To change the URL, reenter the <b>config-url</b> command with a new URL. See the <a href="#">“Changing the Security Context URL” section on page 5-25</a> for more information about changing the URL.</p> |

|        | Command                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                        |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 5 | (Optional)<br><b>member</b> <i>class_name</i><br><br><b>Example:</b><br>hostname(config-ctx)# member gold                                                             | Assigns the context to a resource class. If you do not specify a class, the context belongs to the default class. You can only assign a context to one resource class.                                                                                         |
| Step 6 | (Optional)<br><b>allocate-ips</b> <i>sensor_name</i> [ <i>mapped_name</i> ]<br>[default]<br><br><b>Example:</b><br>hostname(config-ctx)# allocate-ips sensor1 highsec | Assigns an IPS virtual sensor to this context if you have the AIP SSM installed.<br><br>See the “ <a href="#">Assigning Virtual Sensors to a Security Context (ASA 5510 and Higher)</a> ” section on page 55-6 for detailed information about virtual sensors. |

## Examples

The following example sets the admin context to be “administrator,” creates a context called “administrator” on the internal flash memory, and then adds two contexts from an FTP server:

```
hostname(config)# admin-context administrator
hostname(config)# context administrator
hostname(config-ctx)# allocate-interface gigabitethernet0/0.1
hostname(config-ctx)# allocate-interface gigabitethernet0/1.1
hostname(config-ctx)# config-url flash:/admin.cfg

hostname(config-ctx)# context test
hostname(config-ctx)# allocate-interface gigabitethernet0/0.100 int1
hostname(config-ctx)# allocate-interface gigabitethernet0/0.102 int2
hostname(config-ctx)# allocate-interface gigabitethernet0/0.110-gigabitethernet0/0.115
int3-int8
hostname(config-ctx)# config-url ftp://user1:passwd@10.1.1.1/configlets/test.cfg
hostname(config-ctx)# member gold

hostname(config-ctx)# context sample
hostname(config-ctx)# allocate-interface gigabitethernet0/1.200 int1
hostname(config-ctx)# allocate-interface gigabitethernet0/1.212 int2
hostname(config-ctx)# allocate-interface gigabitethernet0/1.230-gigabitethernet0/1.235
int3-int8
hostname(config-ctx)# config-url ftp://user1:passwd@10.1.1.1/configlets/sample.cfg
hostname(config-ctx)# member silver
```

## Automatically Assigning MAC Addresses to Context Interfaces

This section describes how to configure auto-generation of MAC addresses. The MAC address is used to classify packets within a context. See the “[Information About MAC Addresses](#)” section on page 5-11 for more information. See also the “[Viewing Assigned MAC Addresses](#)” section on page 5-35.

### Guidelines

- When you configure a **nameif** command for the interface in a context, the new MAC address is generated immediately. If you enable this feature after you configure context interfaces, then MAC addresses are generated for all interfaces immediately after you enable it. If you disable this feature, the MAC address for each interface reverts to the default MAC address. For example, subinterfaces of GigabitEthernet 0/1 revert to using the MAC address of GigabitEthernet 0/1.

- For the MAC address generation method when not using a prefix (not recommended), see the **mac-address auto** command in the *Cisco ASA 5500 Series Command Reference*.
- In the rare circumstance that the generated MAC address conflicts with another private MAC address in your network, you can manually set the MAC address for the interface within the context. See the [“Configuring the MAC Address” section on page 6-26](#) to manually set the MAC address.

### Detailed Steps

| Command                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mac-address auto prefix</b> <i>prefix</i>                               | Automatically assign private MAC addresses to each context interface.                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Example:</b><br><pre>hostname(config)# mac-address auto prefix 19</pre> | The <i>prefix</i> is a decimal value between 0 and 65535. This prefix is converted to a 4-digit hexadecimal number, and used as part of the MAC address. The prefix ensures that each adaptive security appliance uses unique MAC addresses, so you can have multiple adaptive security appliances on a network segment, for example. See the <a href="#">“MAC Address Format”</a> section for more information about how the prefix is used. |

## Changing Between Contexts and the System Execution Space

If you log in to the system execution space (or the admin context using Telnet or SSH), you can change between contexts and perform configuration and monitoring tasks within each context. The running configuration that you edit in a configuration mode, or that is used in the **copy** or **write** commands, depends on your location. When you are in the system execution space, the running configuration consists only of the system configuration; when you are in a context, the running configuration consists only of that context. For example, you cannot view all running configurations (system plus all contexts) by entering the **show running-config** command. Only the current configuration displays.

To change between the system execution space and a context, or between contexts, see the following commands:

| Command                             | Purpose                                                                                               |
|-------------------------------------|-------------------------------------------------------------------------------------------------------|
| <b>changeto context</b> <i>name</i> | Changes to a context. The prompt changes to the following:<br><code>hostname/name#</code>             |
| <b>changeto system</b>              | Changes to the system execution space. The prompt changes to the following:<br><code>hostname#</code> |

## Managing Security Contexts

This section describes how to manage security contexts and includes the following topics:

- [Removing a Security Context, page 5-24](#)
- [Changing the Admin Context, page 5-24](#)
- [Changing the Security Context URL, page 5-25](#)

- [Reloading a Security Context, page 5-26](#)

## Removing a Security Context

You can only remove a context by editing the system configuration. You cannot remove the current admin context, unless you remove all contexts using the **clear context** command.

### Note

If you use failover, there is a delay between when you remove the context on the active unit and when the context is removed on the standby unit. You might see an error message indicating that the number of interfaces on the active and standby units are not consistent; this error is temporary and can be ignored.

### Prerequisites

Perform this procedure in the system execution space.

### Detailed Steps

| Command                       | Purpose                                                          |
|-------------------------------|------------------------------------------------------------------|
| <b>no context</b> <i>name</i> | Removes a single context. All context commands are also removed. |
| <b>clear context</b>          | Removes all contexts (including the admin context).              |

## Changing the Admin Context

The system configuration does not include any network interfaces or network settings for itself; rather, when the system needs to access network resources (such as downloading the contexts from the server), it uses one of the contexts that is designated as the admin context.

The admin context is just like any other context, except that when a user logs in to the admin context, then that user has system administrator rights and can access the system and all other contexts. The admin context is not restricted in any way, and can be used as a regular context. However, because logging into the admin context grants you administrator privileges over all contexts, you might need to restrict access to the admin context to appropriate users.

### Guidelines

You can set any context to be the admin context, as long as the configuration file is stored in the internal flash memory.

### Prerequisites

Perform this procedure in the system execution space.

## Detailed Steps

| Command                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>admin-context</b> <i>context_name</i><br><br><b>Example:</b><br><pre>hostname(config)# admin-context administrator</pre> | Sets the admin context. Any remote management sessions, such as Telnet, SSH, or HTTPS, that are connected to the admin context are terminated. You must reconnect to the new admin context.<br><br><b>Note</b> A few system commands, including <b>ntp server</b> , identify an interface name that belongs to the admin context. If you change the admin context, and that interface name does not exist in the new admin context, be sure to update any system commands that refer to the interface. |

## Changing the Security Context URL

This section describes how to change the context URL.

### Guidelines

- You cannot change the security context URL without reloading the configuration from the new URL. The adaptive security appliance merges the new configuration with the current running configuration.
- Reentering the same URL also merges the saved configuration with the running configuration.

A merge adds any new commands from the new configuration to the running configuration.

- If the configurations are the same, no changes occur.
- If commands conflict or if commands affect the running of the context, then the effect of the merge depends on the command. You might get errors, or you might have unexpected results. If the running configuration is blank (for example, if the server was unavailable and the configuration was never downloaded), then the new configuration is used.

If you do not want to merge the configurations, you can clear the running configuration, which disrupts any communications through the context, and then reload the configuration from the new URL.

### Prerequisites

Perform this procedure in the system execution space.

## Detailed Steps

|        | Command                                                                                                                                                                                                                                        | Purpose                                                                                              |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|
| Step 1 | <p>(Optional, if you do not want to perform a merge)</p> <pre>changeto context <i>name</i> clear configure all</pre> <p><b>Example:</b><br/> <pre>hostname(config)# changeto context ctx1 hostname/ctx1(config)# clear configure all</pre></p> | Changes to the context and clears its configuration. If you want to perform a merge, skip to Step 2. |
| Step 2 | <pre>changeto system</pre> <p><b>Example:</b><br/> <pre>hostname/ctx1(config)# changeto system hostname(config)#</pre></p>                                                                                                                     | Changes to the system execution space.                                                               |
| Step 3 | <pre>context <i>name</i></pre> <p><b>Example:</b><br/> <pre>hostname(config)# context ctx1</pre></p>                                                                                                                                           | Enters the context configuration mode for the context you want to change.                            |
| Step 4 | <pre>config-url <i>new_url</i></pre> <p><b>Example:</b><br/> <pre>hostname(config)# config-url ftp://user1:passw0rd@10.1.1.1/configlets/c tx1.cfg</pre></p>                                                                                    | Enters the new URL. The system immediately loads the context so that it is running.                  |

## Reloading a Security Context

You can reload the context in two ways:

- Clear the running configuration and then import the startup configuration.  
This action clears most attributes associated with the context, such as connections and NAT tables.
- Remove the context from the system configuration.  
This action clears additional attributes, such as memory allocation, which might be useful for troubleshooting. However, to add the context back to the system requires you to respecify the URL and interfaces.

This section includes the following topics:

- [Reloading by Clearing the Configuration, page 5-26](#)
- [Reloading by Removing and Re-adding the Context, page 5-27](#)

### Reloading by Clearing the Configuration

To reload the context by clearing the context configuration, and reloading the configuration from the URL, perform the following steps.

## Detailed Steps

|        | Command                                                                                                                         | Purpose                                                                                                                                                                                  |
|--------|---------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>changeto context</b> <i>name</i><br><br><b>Example:</b><br>hostname(config)# changeto context ctx1<br>hostname/ctx1(config)# | Changes to the context that you want to reload.                                                                                                                                          |
| Step 2 | <b>clear configure all</b><br><br><b>Example:</b><br>hostname/ctx1(config)# clear configure all                                 | Clears the running configuration. This command clears all connections.                                                                                                                   |
| Step 3 | <b>copy startup-config running-config</b><br><br><b>Example:</b><br>hostname/ctx1(config)# copy startup-config running-config   | Reloads the configuration. The adaptive security appliance copies the configuration from the URL specified in the system configuration. You cannot change the URL from within a context. |

## Reloading by Removing and Re-adding the Context

To reload the context by removing the context and then re-adding it, perform the steps in the following sections:

1. [“Removing a Security Context” section on page 5-24](#)
2. [“Configuring a Security Context” section on page 5-17](#)

# Monitoring Security Contexts

This section describes how to view and monitor context information and includes the following topics:

- [Viewing Context Information, page 5-27](#)
- [Viewing Context Information, page 5-27](#)
- [Viewing Resource Allocation, page 5-29](#)
- [Viewing Resource Usage, page 5-32](#)
- [Monitoring SYN Attacks in Contexts, page 5-33](#)
- [Viewing Assigned MAC Addresses, page 5-35](#)

## Viewing Context Information

From the system execution space, you can view a list of contexts including the name, allocated interfaces, and configuration file URL.

From the system execution space, view all contexts by entering the following command:

| Command                                                            | Purpose                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>show context</b> [ <i>name</i>   <b>detail</b>   <b>count</b> ] | Shows all contexts.<br><br>The <b>detail</b> option shows additional information. See the following sample displays below for more information.<br><br>If you want to show information for a particular context, specify the <i>name</i> .<br><br>The <b>count</b> option shows the total number of contexts. |

The following is sample output from the **show context** command. The following sample display shows three contexts:

```
hostname# show context

Context Name      Interfaces          URL
*admin            GigabitEthernet0/1.100  disk0:/admin.cfg
                  GigabitEthernet0/1.101
contexta          GigabitEthernet0/1.200  disk0:/contexta.cfg
                  GigabitEthernet0/1.201
contextb          GigabitEthernet0/1.300  disk0:/contextb.cfg
                  GigabitEthernet0/1.301
Total active Security Contexts: 3
```

Table 5-2 shows each field description.

**Table 5-2** *show context Fields*

| Field        | Description                                                                           |
|--------------|---------------------------------------------------------------------------------------|
| Context Name | Lists all context names. The context name with the asterisk (*) is the admin context. |
| Interfaces   | The interfaces assigned to the context.                                               |
| URL          | The URL from which the adaptive security appliance loads the context configuration.   |

The following is sample output from the **show context detail** command:

```
hostname# show context detail

Context "admin", has been created, but initial ACL rules not complete
  Config URL: disk0:/admin.cfg
  Real Interfaces: Management0/0
  Mapped Interfaces: Management0/0
  Flags: 0x00000013, ID: 1

Context "ctx", has been created, but initial ACL rules not complete
  Config URL: ctx.cfg
  Real Interfaces: GigabitEthernet0/0.10, GigabitEthernet0/1.20,
                  GigabitEthernet0/2.30
  Mapped Interfaces: int1, int2, int3

Context "system", is a system resource
  Config URL: startup-config
  Real Interfaces:
  Mapped Interfaces: Control0/0, GigabitEthernet0/0,
                  GigabitEthernet0/0.10, GigabitEthernet0/1, GigabitEthernet0/1.10,
```

```
GigabitEthernet0/1.20, GigabitEthernet0/2, GigabitEthernet0/2.30,
GigabitEthernet0/3, Management0/0, Management0/0.1
Flags: 0x00000019, ID: 257
```

```
Context "null", is a system resource
Config URL: ... null ...
Real Interfaces:
Mapped Interfaces:
Flags: 0x00000009, ID: 258
```

See the *Cisco ASA 5500 Series Command Reference* for more information about the **detail** output.

The following is sample output from the **show context count** command:

```
hostname# show context count
Total active contexts: 2
```

## Viewing Resource Allocation

From the system execution space, you can view the allocation for each resource across all classes and class members.

To view the resource allocation, enter the following command:

| Command                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>show resource allocation</b> [ <b>detail</b> ] | Shows the resource allocation. This command shows the resource allocation, but does not show the actual resources being used. See the <a href="#">“Viewing Resource Usage” section on page 5-32</a> for more information about actual resource usage.<br><br>The <b>detail</b> argument shows additional information. See the following sample displays for more information. |

The following sample display shows the total allocation of each resource as an absolute value and as a percentage of the available system resources:

```
hostname# show resource allocation
Resource          Total          % of Avail
Conns [rate]      35000          N/A
Inspects [rate]   35000          N/A
Syslogs [rate]    10500          N/A
Conns              305000         30.50%
Hosts              78842          N/A
SSH                35             35.00%
Telnet             35             35.00%
Xlates             91749          N/A
All                unlimited
```

Table 5-3 shows each field description.

**Table 5-3** *show resource allocation Fields*

| Field      | Description                                                                                                                                                                                                                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Resource   | The name of the resource that you can limit.                                                                                                                                                                                                                                                                     |
| Total      | The total amount of the resource that is allocated across all contexts. The amount is an absolute number of concurrent instances or instances per second. If you specified a percentage in the class definition, the adaptive security appliance converts the percentage to an absolute number for this display. |
| % of Avail | The percentage of the total system resources that is allocated across all contexts, if the resource has a hard system limit. If a resource does not have a system limit, this column shows N/A.                                                                                                                  |

Table 5-4 shows each field description.

**Table 5-4** *show resource allocation detail Fields*

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Resource   | The name of the resource that you can limit.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Class      | The name of each class, including the default class.<br>The All contexts field shows the total values across all classes.                                                                                                                                                                                                                                                                                                                                                                             |
| Mmbrs      | The number of contexts assigned to each class.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Origin     | The origin of the resource limit, as follows: <ul style="list-style-type: none"> <li>A—You set this limit with the <b>all</b> option, instead of as an individual resource.</li> <li>C—This limit is derived from the member class.</li> <li>D—This limit was not defined in the member class, but was derived from the default class. For a context assigned to the default class, the value will be “C” instead of “D.”</li> </ul> The adaptive security appliance can combine “A” with “C” or “D.” |
| Limit      | The limit of the resource per context, as an absolute number. If you specified a percentage in the class definition, the adaptive security appliance converts the percentage to an absolute number for this display.                                                                                                                                                                                                                                                                                  |
| Total      | The total amount of the resource that is allocated across all contexts in the class. The amount is an absolute number of concurrent instances or instances per second. If the resource is unlimited, this display is blank.                                                                                                                                                                                                                                                                           |
| % of Avail | The percentage of the total system resources that is allocated across all contexts in the class. If the resource is unlimited, this display is blank. If the resource does not have a system limit, then this column shows N/A.                                                                                                                                                                                                                                                                       |

## Viewing Resource Usage

From the system execution space, you can view the resource usage for each context and display the system resource usage.

From the system execution space, view the resource usage for each context by entering the following command:

| Command                                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>show resource usage [context context_name   top n   all   summary   system] [resource {resource_name   all}   detail] [counter counter_name [count_threshold]]</pre> | <p>By default, <b>all</b> context usage is displayed; each context is listed separately.</p> <p>Enter the <b>top n</b> keyword to show the contexts that are the top <i>n</i> users of the specified resource. You must specify a single resource type, and not <b>resource all</b>, with this option.</p> <p>The <b>summary</b> option shows all context usage combined.</p> <p>The <b>system</b> option shows all context usage combined, but shows the system limits for resources instead of the combined context limits.</p> <p>For the <b>resource resource_name</b>, see <a href="#">Table 5-1</a> for available resource names. See also the <b>show resource type</b> command. Specify <b>all</b> (the default) for all types.</p> <p>The <b>detail</b> option shows the resource usage of all resources, including those you cannot manage. For example, you can view the number of TCP intercepts.</p> <p>The <b>counter counter_name</b> is one of the following keywords:</p> <ul style="list-style-type: none"> <li>• <b>current</b>—Shows the active concurrent instances or the current rate of the resource.</li> <li>• <b>denied</b>—Shows the number of instances that were denied because they exceeded the resource limit shown in the Limit column.</li> <li>• <b>peak</b>—Shows the peak concurrent instances, or the peak rate of the resource since the statistics were last cleared, either using the <b>clear resource usage</b> command or because the device rebooted.</li> <li>• <b>all</b>—(Default) Shows all statistics.</li> </ul> <p>The <i>count_threshold</i> sets the number above which resources are shown. The default is 1. If the usage of the resource is below the number you set, then the resource is not shown. If you specify <b>all</b> for the counter name, then the <i>count_threshold</i> applies to the current usage.</p> <p><b>Note</b> To show all resources, set the <i>count_threshold</i> to 0.</p> |

The following is sample output from the **show resource usage context** command, which shows the resource usage for the admin context:

```
hostname# show resource usage context admin
```

| Resource | Current | Peak | Limit | Denied | Context |
|----------|---------|------|-------|--------|---------|
| Telnet   | 1       | 1    | 5     | 0      | admin   |
| Conns    | 44      | 55   | N/A   | 0      | admin   |
| Hosts    | 45      | 56   | N/A   | 0      | admin   |

The following is sample output from the **show resource usage summary** command, which shows the resource usage for all contexts and all resources. This sample shows the limits for 6 contexts.

```
hostname# show resource usage summary
```

| Resource        | Current | Peak | Limit      | Denied | Context |
|-----------------|---------|------|------------|--------|---------|
| Syslogs [rate]  | 1743    | 2132 | N/A        | 0      | Summary |
| Conns           | 584     | 763  | 280000 (S) | 0      | Summary |
| Xlates          | 8526    | 8966 | N/A        | 0      | Summary |
| Hosts           | 254     | 254  | N/A        | 0      | Summary |
| Conns [rate]    | 270     | 535  | N/A        | 1704   | Summary |
| Inspects [rate] | 270     | 535  | N/A        | 0      | Summary |

S = System: Combined context limits exceed the system limit; the system limit is shown.

The following is sample output from the **show resource usage summary** command, which shows the limits for 25 contexts. Because the context limit for Telnet and SSH connections is 5 per context, then the combined limit is 125. The system limit is only 100, so the system limit is shown.

```
hostname# show resource usage summary
```

| Resource | Current | Peak | Limit   | Denied | Context |
|----------|---------|------|---------|--------|---------|
| Telnet   | 1       | 1    | 100 [S] | 0      | Summary |
| SSH      | 2       | 2    | 100 [S] | 0      | Summary |
| Conns    | 56      | 90   | N/A     | 0      | Summary |
| Hosts    | 89      | 102  | N/A     | 0      | Summary |

S = System: Combined context limits exceed the system limit; the system limit is shown.

The following is sample output from the **show resource usage system** command, which shows the resource usage for all contexts, but it shows the system limit instead of the combined context limits. The **counter all 0** option is used to show resources that are not currently in use. The Denied statistics indicate how many times the resource was denied due to the system limit, if available.

```
hostname# show resource usage system counter all 0
```

| Resource        | Current | Peak | Limit  | Denied | Context |
|-----------------|---------|------|--------|--------|---------|
| Telnet          | 0       | 0    | 100    | 0      | System  |
| SSH             | 0       | 0    | 100    | 0      | System  |
| ASDM            | 0       | 0    | 32     | 0      | System  |
| Syslogs [rate]  | 1       | 18   | N/A    | 0      | System  |
| Conns           | 0       | 1    | 280000 | 0      | System  |
| Xlates          | 0       | 0    | N/A    | 0      | System  |
| Hosts           | 0       | 2    | N/A    | 0      | System  |
| Conns [rate]    | 1       | 1    | N/A    | 0      | System  |
| Inspects [rate] | 0       | 0    | N/A    | 0      | System  |

## Monitoring SYN Attacks in Contexts

The adaptive security appliance prevents SYN attacks using TCP Intercept. TCP Intercept uses the SYN cookies algorithm to prevent TCP SYN-flooding attacks. A SYN-flooding attack consists of a series of SYN packets usually originating from spoofed IP addresses. The constant flood of SYN packets keeps the server SYN queue full, which prevents it from servicing connection requests. When the embryonic connection threshold of a connection is crossed, the adaptive security appliance acts as a proxy for the server and generates a SYN-ACK response to the client SYN request. When the adaptive security appliance receives an ACK back from the client, it can then authenticate the client and allow the connection to the server.

Monitor SYN attacks using the following commands:

| Command                                   | Purpose                                                                               |
|-------------------------------------------|---------------------------------------------------------------------------------------|
| <b>show perfmon</b>                       | Monitors the rate of attacks for individual contexts.                                 |
| <b>show resource usage detail</b>         | Monitors the amount of resources being used by TCP intercept for individual contexts. |
| <b>show resource usage summary detail</b> | Monitors the resources being used by TCP intercept for the entire system.             |

The following is sample output from the **show perfmon** command that shows the rate of TCP intercepts for a context called admin.

```
hostname/admin# show perfmon

Context:admin
PERFMON STATS:   Current      Average
Xlates           0/s          0/s
Connections      0/s          0/s
TCP Conns        0/s          0/s
UDP Conns        0/s          0/s
URL Access       0/s          0/s
URL Server Req   0/s          0/s
WebSns Req       0/s          0/s
TCP Fixup        0/s          0/s
HTTP Fixup       0/s          0/s
FTP Fixup        0/s          0/s
AAA Authen       0/s          0/s
AAA Author       0/s          0/s
AAA Account      0/s          0/s
TCP Intercept    322779/s     322779/s
```

The following is sample output from the **show resource usage detail** command that shows the amount of resources being used by TCP Intercept for individual contexts. (Sample text in *italics* shows the TCP intercept information.)

```
hostname(config)# show resource usage detail

Resource          Current      Peak      Limit      Denied Context
memory            843732     847288   unlimited   0 admin

## Viewing Assigned MAC Addresses

You can view auto-generated MAC addresses within the system configuration or within the context. This section includes the following topics:

- [Viewing MAC Addresses in the System Configuration, page 5-36](#)
- [Viewing MAC Addresses Within a Context, page 5-37](#)

## Viewing MAC Addresses in the System Configuration

This section describes how to view MAC addresses in the system configuration.

### Guidelines

If you manually assign a MAC address to an interface, but also have auto-generation enabled, the auto-generated address continues to show in the configuration even though the manual MAC address is the one that is in use. If you later remove the manual MAC address, the auto-generated one shown will be used.

### Detailed Steps

| Command                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>show running-config all context [name]</code> | Shows the assigned MAC addresses from the system execution space.<br><br>The <b>all</b> option is required to view the assigned MAC addresses. Although this command is user-configurable in global configuration mode only, the <b>mac-address auto</b> command appears as a read-only entry in the configuration for each context along with the assigned MAC address. Only allocated interfaces that are configured with a <b>nameif</b> command within the context have a MAC address assigned. |

### Examples

The following output from the **show running-config all context admin** command shows the primary and standby MAC address assigned to the Management0/0 interface:

```
hostname# show running-config all context admin

context admin
  allocate-interface Management0/0
  mac-address auto Management0/0 a24d.0000.1440 a24d.0000.1441
  config-url disk0:/admin.cfg
```

The following output from the **show running-config all context** command shows all the MAC addresses (primary and standby) for all context interfaces. Note that because the GigabitEthernet0/0 and GigabitEthernet0/1 main interfaces are not configured with a **nameif** command inside the contexts, no MAC addresses have been generated for them.

```
hostname# show running-config all context

admin-context admin
context admin
  allocate-interface Management0/0
  mac-address auto Management0/0 a2d2.0400.125a a2d2.0400.125b
  config-url disk0:/admin.cfg
!

context CTX1
  allocate-interface GigabitEthernet0/0
  allocate-interface GigabitEthernet0/0.1-GigabitEthernet0/0.5
  mac-address auto GigabitEthernet0/0.1 a2d2.0400.11bc a2d2.0400.11bd
  mac-address auto GigabitEthernet0/0.2 a2d2.0400.11c0 a2d2.0400.11c1
  mac-address auto GigabitEthernet0/0.3 a2d2.0400.11c4 a2d2.0400.11c5
  mac-address auto GigabitEthernet0/0.4 a2d2.0400.11c8 a2d2.0400.11c9
```

```

mac-address auto GigabitEthernet0/0.5 a2d2.0400.11cc a2d2.0400.11cd
allocate-interface GigabitEthernet0/1
allocate-interface GigabitEthernet0/1.1-GigabitEthernet0/1.3
mac-address auto GigabitEthernet0/1.1 a2d2.0400.120c a2d2.0400.120d
mac-address auto GigabitEthernet0/1.2 a2d2.0400.1210 a2d2.0400.1211
mac-address auto GigabitEthernet0/1.3 a2d2.0400.1214 a2d2.0400.1215
config-url disk0:/CTX1.cfg
!

context CTX2
allocate-interface GigabitEthernet0/0
allocate-interface GigabitEthernet0/0.1-GigabitEthernet0/0.5
mac-address auto GigabitEthernet0/0.1 a2d2.0400.11ba a2d2.0400.11bb
mac-address auto GigabitEthernet0/0.2 a2d2.0400.11be a2d2.0400.11bf
mac-address auto GigabitEthernet0/0.3 a2d2.0400.11c2 a2d2.0400.11c3
mac-address auto GigabitEthernet0/0.4 a2d2.0400.11c6 a2d2.0400.11c7
mac-address auto GigabitEthernet0/0.5 a2d2.0400.11ca a2d2.0400.11cb
allocate-interface GigabitEthernet0/1
allocate-interface GigabitEthernet0/1.1-GigabitEthernet0/1.3
mac-address auto GigabitEthernet0/1.1 a2d2.0400.120a a2d2.0400.120b
mac-address auto GigabitEthernet0/1.2 a2d2.0400.120e a2d2.0400.120f
mac-address auto GigabitEthernet0/1.3 a2d2.0400.1212 a2d2.0400.1213
config-url disk0:/CTX2.cfg
!
```

## Viewing MAC Addresses Within a Context

This section describes how to view MAC addresses within a context.

### Detailed Steps

| Command                                             | Purpose                                                            |
|-----------------------------------------------------|--------------------------------------------------------------------|
| <b>show interface   include (Interface)   (MAC)</b> | Shows the MAC address in use by each interface within the context. |

### Examples

For example:

```

hostname/context# show interface | include (Interface) | (MAC)

Interface GigabitEthernet1/1.1 "g1/1.1", is down, line protocol is down
MAC address a201.0101.0600, MTU 1500
Interface GigabitEthernet1/1.2 "g1/1.2", is down, line protocol is down
MAC address a201.0102.0600, MTU 1500
Interface GigabitEthernet1/1.3 "g1/1.3", is down, line protocol is down
MAC address a201.0103.0600, MTU 1500
...
```

#### Note

The **show interface** command shows the MAC address in use; if you manually assign a MAC address and also have auto-generation enabled, then you can only view the unused auto-generated address from within the system configuration.

# Configuration Examples for Multiple Context Mode

The following example:

- Automatically sets the MAC addresses in contexts.
- Sets the default class limit for conns to 10 percent instead of unlimited.
- Creates a gold resource class.
- Sets the admin context to be “administrator.”
- Creates a context called “administrator” on the internal flash memory to be part of the default resource class.
- Adds two contexts from an FTP server as part of the gold resource class.

```
hostname(config)# mac-address auto prefix 19

hostname(config)# class default
hostname(config-class)# limit-resource conns 10%

hostname(config)# class gold
hostname(config-class)# limit-resource mac-addresses 10000
hostname(config-class)# limit-resource conns 15%
hostname(config-class)# limit-resource rate conns 1000
hostname(config-class)# limit-resource rate inspects 500
hostname(config-class)# limit-resource hosts 9000
hostname(config-class)# limit-resource asdm 5
hostname(config-class)# limit-resource ssh 5
hostname(config-class)# limit-resource rate syslogs 5000
hostname(config-class)# limit-resource telnet 5
hostname(config-class)# limit-resource xlates 36000

hostname(config)# admin-context administrator
hostname(config)# context administrator
hostname(config-ctx)# allocate-interface gigabitethernet0/0.1
hostname(config-ctx)# allocate-interface gigabitethernet0/1.1
hostname(config-ctx)# config-url flash:/admin.cfg

hostname(config-ctx)# context test
hostname(config-ctx)# allocate-interface gigabitethernet0/0.100 int1
hostname(config-ctx)# allocate-interface gigabitethernet0/0.102 int2
hostname(config-ctx)# allocate-interface gigabitethernet0/0.110-gigabitethernet0/0.115
int3-int8
hostname(config-ctx)# config-url ftp://user1:passwd@10.1.1.1/configlets/test.cfg
hostname(config-ctx)# member gold

hostname(config-ctx)# context sample
hostname(config-ctx)# allocate-interface gigabitethernet0/1.200 int1
hostname(config-ctx)# allocate-interface gigabitethernet0/1.212 int2
hostname(config-ctx)# allocate-interface gigabitethernet0/1.230-gigabitethernet0/1.235
int3-int8
hostname(config-ctx)# config-url ftp://user1:passwd@10.1.1.1/configlets/sample.cfg
hostname(config-ctx)# member gold
```

# Feature History for Multiple Context Mode

Table 5-5 lists each feature change and the platform release in which it was implemented.

**Table 5-5** Feature History for Multiple Context Mode

| Feature Name                                  | Platform Releases | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Multiple security contexts                    | 7.0(1)            | Multiple context mode was introduced.<br><br>The following commands were introduced: <b>context</b> , <b>mode</b> , and <b>class</b> .                                                                                                                                                                                                                                                                                                                                                                 |
| Automatic MAC address assignment              | 7.2(1)            | Automatic assignment of MAC address to context interfaces was introduced.<br><br>The following command was introduced: <b>mac-address auto</b> .<br>.                                                                                                                                                                                                                                                                                                                                                  |
| Resource management                           | 7.2(1)            | Resource management was introduced.<br><br>The following commands were introduced: <b>class</b> , <b>limit-resource</b> , and <b>member</b> .<br>.                                                                                                                                                                                                                                                                                                                                                     |
| Virtual sensors for IPS                       | 8.0(2)            | The AIP SSM running IPS software Version 6.0 and above can run multiple virtual sensors, which means you can configure multiple security policies on the AIP SSM. You can assign each context or single mode adaptive security appliance to one or more virtual sensors, or you can assign multiple security contexts to the same virtual sensor.<br><br>The following command was introduced: <b>allocate-ips</b> .<br>.                                                                              |
| Automatic MAC address assignment enhancements | 8.0(5)/8.2(2)     | The MAC address format was changed to use a prefix, to use a fixed starting value (A2), and to use a different scheme for the primary and secondary unit MAC addresses in a failover pair. The MAC addresses are also now persistent across reloads. The command parser now checks if auto-generation is enabled; if you want to also manually assign a MAC address, you cannot start the manual MAC address with A2.<br><br>The following command was modified: <b>mac-address auto prefix</b> .<br>. |

# CHAPTER 6

## Configuring Interfaces

---

This chapter describes how to configure interfaces, including Ethernet parameters, switch ports (for the ASA 5505), VLAN subinterfaces, and IP addressing.

The procedure to configure interfaces varies depending on several factors: the ASA 5505 vs. other models; routed vs. transparent mode; and single vs. multiple mode. This chapter describes how to configure interfaces for each of these variables.

### Note

If your adaptive security appliance has the default factory configuration, many interface parameters are already configured. This chapter assumes you do *not* have a factory default configuration, or that if you have a default configuration, that you need to change the configuration. For information about the factory default configurations, see the [“Factory Default Configurations” section on page 2-1](#).

This chapter includes the following sections:

- [Information About Interfaces, page 6-1](#)
- [Licensing Requirements for Interfaces, page 6-6](#)
- [Guidelines and Limitations, page 6-7](#)
- [Default Settings, page 6-8](#)
- [Starting Interface Configuration \(ASA 5510 and Higher\), page 6-8](#)
- [Starting Interface Configuration \(ASA 5505\), page 6-16](#)
- [Completing Interface Configuration \(All Models\), page 6-22](#)
- [Allowing Same Security Level Communication, page 6-30](#)
- [Enabling Jumbo Frame Support \(ASA 5580\), page 6-31](#)
- [Monitoring Interfaces, page 6-32](#)
- [Configuration Examples for Interfaces, page 6-32](#)
- [Feature History for Interfaces, page 6-34](#)

## Information About Interfaces

This section describes adaptive security appliance interfaces and includes the following topics:

- [ASA 5505 Interfaces, page 6-2](#)
- [Auto-MDI/MDIX Feature, page 6-5](#)

- [Security Levels](#), page 6-5
- [Dual IP Stack](#), page 6-6
- [Management Interface \(ASA 5510 and Higher\)](#), page 6-6

## ASA 5505 Interfaces

This section describes the ports and interfaces of the ASA 5505 adaptive security appliance and includes the following topics:

- [Understanding ASA 5505 Ports and Interfaces](#), page 6-2
- [Maximum Active VLAN Interfaces for Your License](#), page 6-2
- [VLAN MAC Addresses](#), page 6-4
- [Power over Ethernet](#), page 6-4

### Understanding ASA 5505 Ports and Interfaces

The ASA 5505 adaptive security appliance supports a built-in switch. There are two kinds of ports and interfaces that you need to configure:

- **Physical switch ports**—The adaptive security appliance has 8 Fast Ethernet switch ports that forward traffic at Layer 2, using the switching function in hardware. Two of these ports are PoE ports. See the [“Power over Ethernet” section on page 6-4](#) for more information. You can connect these interfaces directly to user equipment such as PCs, IP phones, or a DSL modem. Or you can connect to another switch.
- **Logical VLAN interfaces**—In routed mode, these interfaces forward traffic between VLAN networks at Layer 3, using the configured security policy to apply firewall and VPN services. In transparent mode, these interfaces forward traffic between the VLANs on the same network at Layer 2, using the configured security policy to apply firewall services. See the [“Maximum Active VLAN Interfaces for Your License”](#) section for more information about the maximum VLAN interfaces. VLAN interfaces let you divide your equipment into separate VLANs, for example, home, business, and Internet VLANs.

To segregate the switch ports into separate VLANs, you assign each switch port to a VLAN interface. Switch ports on the same VLAN can communicate with each other using hardware switching. But when a switch port on VLAN 1 wants to communicate with a switch port on VLAN 2, then the adaptive security appliance applies the security policy to the traffic and routes or bridges between the two VLANs.

### Maximum Active VLAN Interfaces for Your License

In transparent firewall mode, you can configure the following VLANs depending on your license:

- Base license—2 active VLANs.
- Security Plus license—3 active VLANs, one of which must be for failover.

In routed mode, you can configure the following VLANs depending on your license: Base license

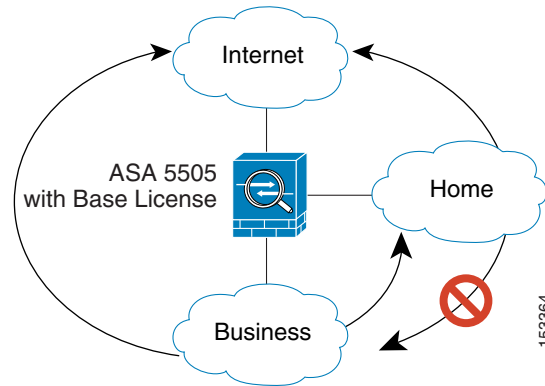

- Base license—3 active VLANs. The third VLAN can only be configured to initiate traffic to one other VLAN. See [Figure 6-1](#) for more information.
- Security Plus license—20 active VLANs.

**Note**

An *active VLAN* is a VLAN with a **nameif** command configured.

With the Base license, the third VLAN can only be configured to initiate traffic to one other VLAN. See [Figure 6-1](#) for an example network where the Home VLAN can communicate with the Internet, but cannot initiate contact with Business.

**Figure 6-1 ASA 5505 Adaptive Security Appliance with Base License**

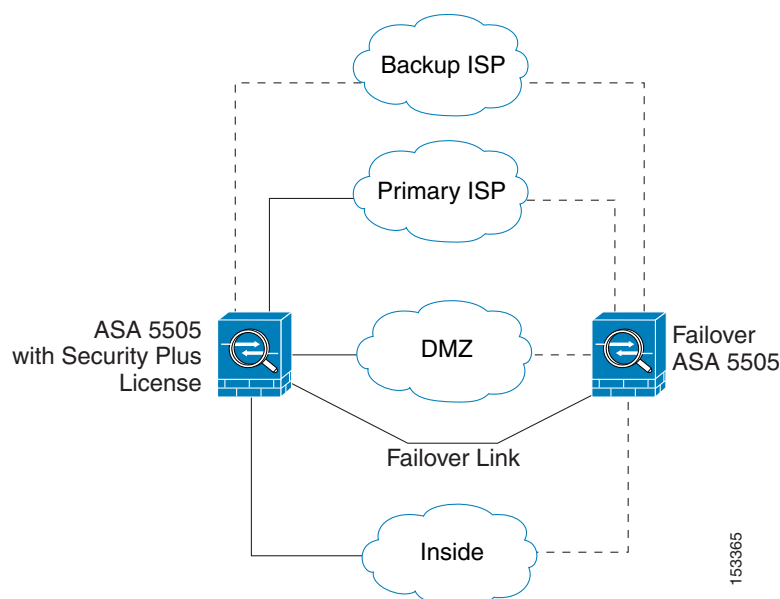

With the Security Plus license, you can configure 20 VLAN interfaces, including a VLAN interface for failover and a VLAN interface as a backup link to your ISP. You can configure the backup interface to not pass through traffic unless the route through the primary interface fails. You can configure trunk ports to accommodate multiple VLANs per port.

**Note**

The ASA 5505 adaptive security appliance supports Active/Standby failover, but not Stateful Failover.

See [Figure 6-2](#) for an example network.

**Figure 6-2** ASA 5505 Adaptive Security Appliance with Security Plus License

## VLAN MAC Addresses

- Routed firewall mode—All VLAN interfaces share a MAC address. Ensure that any connected switches can support this scenario. If the connected switches require unique MAC addresses, you can manually assign MAC addresses. See the [“Configuring the MAC Address”](#) section on page 6-26.
- Transparent firewall mode—Each VLAN has a unique MAC address. You can override the generated MAC addresses if desired by manually assigning MAC addresses. See the [“Configuring the MAC Address”](#) section on page 6-26.

## Power over Ethernet

Ethernet 0/6 and Ethernet 0/7 support PoE for devices such as IP phones or wireless access points. If you install a non-PoE device or do not connect to these switch ports, the adaptive security appliance does not supply power to the switch ports.

If you shut down the switch port using the **shutdown** command, you disable power to the device. Power is restored when you enable the port using the **no shutdown** command. See the [“Configuring and Enabling Switch Ports as Access Ports”](#) section on page 6-17 for more information about shutting down a switch port.

To view the status of PoE switch ports, including the type of device connected (Cisco or IEEE 802.3af), use the **show power inline** command.

## Monitoring Traffic Using SPAN

If you want to monitor traffic that enters or exits one or more switch ports, you can enable SPAN, also known as switch port monitoring. The port for which you enable SPAN (called the destination port) receives a copy of every packet transmitted or received on a specified source port. The SPAN feature lets you attach a sniffer to the destination port so you can monitor all traffic; without SPAN, you would have to attach a sniffer to every port you want to monitor. You can only enable SPAN for one destination port.

See the **switchport monitor** command in the *Cisco ASA 5500 Series Command Reference* for more information.

## Auto-MDI/MDIX Feature

For RJ-45 interfaces, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase.

For the ASA 5510 and higher, either the speed or duplex must be set to auto-negotiate to enable Auto-MDI/MDIX for the interface. If you explicitly set both the speed and duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled.

For Gigabit Ethernet, when the speed and duplex are set to 1000 and full, then the interface always auto-negotiates; therefore Auto-MDI/MDIX is always enabled and you cannot disable it.

For the ASA 5505, you cannot disable Auto-MDI/MDIX.

## Security Levels

Each interface must have a security level from 0 (lowest) to 100 (highest). For example, you should assign your most secure network, such as the inside host network, to level 100. While the outside network connected to the Internet can be level 0. Other networks, such as DMZs can be in between. You can assign interfaces to the same security level. See the [“Allowing Same Security Level Communication” section on page 6-30](#) for more information.

The level controls the following behavior:

- Network access—By default, there is an implicit permit from a higher security interface to a lower security interface (outbound). Hosts on the higher security interface can access any host on a lower security interface. You can limit access by applying an access list to the interface.

If you enable communication for same security interfaces (see the [“Allowing Same Security Level Communication” section on page 6-30](#)), there is an implicit permit for interfaces to access other interfaces on the same security level or lower.

- Inspection engines—Some application inspection engines are dependent on the security level. For same security interfaces, inspection engines apply to traffic in either direction.
  - NetBIOS inspection engine—Applied only for outbound connections.
  - SQL\*Net inspection engine—If a control connection for the SQL\*Net (formerly OraServ) port exists between a pair of hosts, then only an inbound data connection is permitted through the adaptive security appliance.
- Filtering—HTTP(S) and FTP filtering applies only for outbound connections (from a higher level to a lower level).

If you enable communication for same security interfaces, you can filter traffic in either direction.

- **established** command—This command allows return connections from a lower security host to a higher security host if there is already an established connection from the higher level host to the lower level host.

If you enable communication for same security interfaces, you can configure **established** commands for both directions.

## Dual IP Stack

The adaptive security appliance supports the configuration of both IPv6 and IPv4 on an interface. You do not need to enter any special commands to do so; simply enter the IPv4 configuration commands and IPv6 configuration commands as you normally would. Make sure you configure a default route for both IPv4 and IPv6.

## Management Interface (ASA 5510 and Higher)

The management interface is designed for management traffic only, and is specified as **management slot/port** in commands. You can, however, use it for through traffic if desired (see the **management-only** command). In transparent firewall mode, you can use the management interface (for management purposes) in addition to the two interfaces allowed for through traffic. You can also add subinterfaces to the management interface to provide management in each security context for multiple context mode.

### Note

In transparent firewall mode, the management interface updates the MAC address table in the same manner as a data interface; therefore you should not connect both a management and a data interface to the same switch unless you configure one of the switch ports as a routed port (by default Cisco Catalyst switches share a MAC address for all VLAN switch ports). Otherwise, if traffic arrives on the management interface from the physically-connected switch, then the adaptive security appliance updates the MAC address table to use the *management* interface to access the switch, instead of the data interface. This action causes a temporary traffic interruption; the adaptive security appliance will not re-update the MAC address table for packets from the switch to the data interface for at least 30 seconds for security reasons.

## Licensing Requirements for Interfaces

The following table shows the licensing requirements for VLANs:

| Model    | License Requirement                                                                                                              |
|----------|----------------------------------------------------------------------------------------------------------------------------------|
| ASA 5505 | Base License: 3 (2 regular zones and 1 restricted zone that can only communicate with 1 other zone)<br>Security Plus License: 20 |
| ASA 5510 | Base License: 50<br>Security Plus License: 100                                                                                   |
| ASA 5520 | Base License: 150                                                                                                                |
| ASA 5540 | Base License: 200                                                                                                                |

| Model    | License Requirement |
|----------|---------------------|
| ASA 5550 | Base License: 250   |
| ASA 5580 | Base License: 250   |

The following table shows the licensing requirements for VLAN trunks:

| Model            | License Requirement                              |
|------------------|--------------------------------------------------|
| ASA 5505         | Base License: None.<br>Security Plus License: 8. |
| All other models | N/A                                              |

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

- In multiple context mode, configure the physical interfaces in the system execution space according to the [“Starting Interface Configuration \(ASA 5510 and Higher\)”](#) section on page 6-8.
- Then, configure the logical interface parameters in the context execution space according to the [“Completing Interface Configuration \(All Models\)”](#) section on page 6-22.

### Firewall Mode Guidelines

Transparent firewall mode allows only two interfaces to pass through traffic; however, on the ASA 5510 and higher adaptive security appliance, you can use the Management 0/0 or 0/1 interface (either the physical interface or a subinterface) as a third interface for management traffic. The mode is not configurable in this case and must always be management-only.

### Failover Guidelines

Do not finish configuring failover interfaces with the procedures in [“Completing Interface Configuration \(All Models\)”](#) section on page 6-22. See the [“Configuring Active/Standby Failover”](#) section on page 59-7 or the [“Configuring Active/Active Failover”](#) section on page 58-8 to configure the failover and state links. In multiple context mode, failover interfaces are configured in the system configuration.

### IPv6 Guidelines

- Supports IPv6.
- In transparent mode on a per interface basis, you can only configure the link-local address; you configure the global address as the management address for the entire unit, but not per interface. Because configuring the management global IP address automatically configures the link-local addresses per interface, the only IPv6 configuration you need to perform is to set the management IP address according to the [“Configuring the IPv6 Address”](#) section on page 7-14.

### Model Guidelines

Subinterfaces are not available for the ASA 5505 adaptive security appliance.

# Default Settings

This section lists default settings for interfaces if you do not have a factory default configuration. For information about the factory default configurations, see the [“Factory Default Configurations” section on page 2-1](#).

## Default Security Level

The default security level is 0. If you name an interface “inside” and you do not set the security level explicitly, then the adaptive security appliance sets the security level to 100.

### Note

If you change the security level of an interface, and you do not want to wait for existing connections to time out before the new security information is used, you can clear the connections using the **clear local-host** command.

## Default State of Interfaces

The default state of an interface depends on the type and the context mode.

In multiple context mode, all allocated interfaces are enabled by default, no matter what the state of the interface is in the system execution space. However, for traffic to pass through the interface, the interface also has to be enabled in the system execution space. If you shut down an interface in the system execution space, then that interface is down in all contexts that share it.

In single mode or in the system execution space, interfaces have the following default states:

- Physical interfaces and switch ports—Disabled.
- Redundant Interfaces—Enabled. However, for traffic to pass through the redundant interface, the member physical interfaces must also be enabled.
- Subinterfaces or VLANs—Enabled. However, for traffic to pass through the subinterface, the physical interface must also be enabled.

## Default Speed and Duplex

- By default, the speed and duplex for copper (RJ-45) interfaces are set to auto-negotiate.
- The fiber interface for the ASA 5550 and the 4GE SSM has a fixed speed and does not support duplex, but you can set the interface to negotiate link parameters (the default) or not to negotiate.
- For fiber interfaces for the ASA 5580, the speed is set for automatic link negotiation.

## Default Connector Type

The ASA 5550 adaptive security appliance and the 4GE SSM for the ASA 5510 and higher adaptive security appliance include two connector types: copper RJ-45 and fiber SFP. RJ-45 is the default. You can configure the adaptive security appliance to use the fiber SFP connectors.

## Default MAC Addresses

By default, the physical interface uses the burned-in MAC address, and all subinterfaces of a physical interface use the same burned-in MAC address.

# Starting Interface Configuration (ASA 5510 and Higher)

This section includes tasks for starting your interface configuration for the ASA 5510 and higher.

**Note**

For multiple context mode, complete all tasks in this section in the system execution space. To change from the context to the system execution space, enter the **changeto system** command.

For ASA 5505 configuration, see the “[Starting Interface Configuration \(ASA 5505\)](#)” section on [page 6-16](#).

This section includes the following topics:

- [Task Flow for Starting Interface Configuration](#), page 6-9
- [Configuring a Redundant Interface](#), page 6-11
- [Enabling the Physical Interface and Configuring Ethernet Parameters](#), page 6-9
- [Configuring VLAN Subinterfaces and 802.1Q Trunking](#), page 6-14
- [Assigning Interfaces to Contexts and Automatically Assigning MAC Addresses \(Multiple Context Mode\)](#), page 6-15

## Task Flow for Starting Interface Configuration

To start configuring interfaces, perform the following steps:

- 
- |               |                                                                                                                                                                                                                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | (Multiple context mode) Complete all tasks in this section in the system execution space. To change from the context to the system execution space, enter the <b>changeto system</b> command.                                                                                                                                                 |
| <b>Step 2</b> | Enable the physical interface, and optionally change Ethernet parameters. See the “ <a href="#">Enabling the Physical Interface and Configuring Ethernet Parameters</a> ” section on <a href="#">page 6-9</a> .<br><br>Physical interfaces are disabled by default.                                                                           |
| <b>Step 3</b> | (Optional) Configure redundant interface pairs. See the “ <a href="#">Configuring a Redundant Interface</a> ” section on <a href="#">page 6-11</a> .<br><br>A logical redundant interface pairs an active and a standby physical interface. When the active interface fails, the standby interface becomes active and starts passing traffic. |
| <b>Step 4</b> | (Optional) Configure VLAN subinterfaces. See the “ <a href="#">Configuring VLAN Subinterfaces and 802.1Q Trunking</a> ” section on <a href="#">page 6-14</a> .                                                                                                                                                                                |
| <b>Step 5</b> | (Multiple context mode only) Assign interfaces to contexts and automatically assign unique MAC addresses to context interfaces. See the “ <a href="#">Assigning Interfaces to Contexts and Automatically Assigning MAC Addresses (Multiple Context Mode)</a> ” section on <a href="#">page 6-15</a> .                                         |
| <b>Step 6</b> | Complete the interface configuration according to the “ <a href="#">Completing Interface Configuration (All Models)</a> ” section on <a href="#">page 6-22</a> .                                                                                                                                                                              |
- 

## Enabling the Physical Interface and Configuring Ethernet Parameters

This section describes how to:

- Enable the physical interface
- Set a specific speed and duplex (if available)
- Enable pause frames for flow control (ASA 5580 10 Gigabit Ethernet only).

## Prerequisites

For multiple context mode, complete this procedure in the system execution space. To change from the context to the system execution space, enter the **changeto system** command.

## Detailed Steps

- Step 1** To specify the interface you want to configure, enter the following command:

```
hostname(config)# interface physical_interface
hostname(config-if)#
```

where the *physical\_interface* ID includes the type, slot, and port number as *type[slot/port]*.

The physical interface types include the following:

- **ethernet**
- **gigabitethernet**
- **tengigabitethernet**
- **management**

Enter the type followed by *slot/port*, for example, **gigabitethernet0/1** or **ethernet 0/1**.

- Step 2** (Optional) To set the media type to SFP, if available for your model, enter the following command:

```
hostname(config-if)# media-type sfp
```

To restore the default RJ-45, enter the **media-type rj45** command.

- Step 3** (Optional) To set the speed, enter the following command:

```
hostname(config-if)# speed {auto | 10 | 100 | 1000 | nonegotiate}
```

For copper interfaces, the default setting is **auto**.

For SFP interfaces, the default setting is **no speed nonegotiate**, which sets the speed to the maximum speed and enables link negotiation for flow-control parameters and remote fault information. The **nonegotiate** keyword is the only keyword available for SFP interfaces. The **speed nonegotiate** command disables link negotiation.

- Step 4** (Optional) To set the duplex for copper interfaces, enter the following command:

```
hostname(config-if)# duplex {auto | full | half}
```

The **auto** setting is the default.

- Step 5** (Optional; ASA 5580 only) To enable pause (XOFF) frames for flow control on 10 Gigabit Ethernet interfaces, enter the following command:

```
hostname(config-if)# flowcontrol send on [low_water high_water pause_time] [noconfirm]
```

If you have a traffic burst, dropped packets can occur if the burst exceeds the buffering capacity of the FIFO buffer on the NIC and the receive ring buffers. Enabling pause frames for flow control can alleviate this issue. Pause (XOFF) and XON frames are generated automatically by the NIC hardware based on the FIFO buffer usage. A pause frame is sent when the buffer usage exceeds the high-water mark. The default *high\_water* value is 128 KB; you can set it between 0 and 511. After a pause is sent, an XON frame can be sent when the buffer usage is reduced below the low-water mark. By default, the *low\_water* value is 64 KB; you can set it between 0 and 511. The link partner can resume traffic after receiving an XON, or after the XOFF expires, as controlled by the timer value in the pause frame. The default *pause\_time* value is 26624; you can set it between 0 and 65535. If the buffer usage is consistently above the high-water mark, pause frames are sent repeatedly, controlled by the pause refresh threshold value.

When you use this command, you see the following warning:

Changing flow-control parameters will reset the interface. Packets may be lost during the reset.

Proceed with flow-control changes?

To change the parameters without being prompted, use the **noconfirm** keyword.

**Note** Only flow control frames defined in 802.3x are supported. Priority-based flow control is not supported.

**Step 6** To enable the interface, enter the following command:

```
hostname(config-if)# no shutdown
```

To disable the interface, enter the **shutdown** command. If you enter the **shutdown** command, you also shut down all subinterfaces. If you shut down an interface in the system execution space, then that interface is shut down in all contexts that share it.

## What to Do Next

Optional Tasks:

- Configure redundant interface pairs. See the [“Configuring a Redundant Interface”](#) section on page 6-11.
- Configure VLAN subinterfaces. See the [“Configuring VLAN Subinterfaces and 802.1Q Trunking”](#) section on page 6-14.

Required Tasks:

- For multiple context mode, assign interfaces to contexts and automatically assign unique MAC addresses to context interfaces. See the [“Assigning Interfaces to Contexts and Automatically Assigning MAC Addresses \(Multiple Context Mode\)”](#) section on page 6-15.
- For single context mode, complete the interface configuration. See the [“Completing Interface Configuration \(All Models\)”](#) section on page 6-22.

## Configuring a Redundant Interface

A logical redundant interface consists of a pair of physical interfaces: an active and a standby interface. When the active interface fails, the standby interface becomes active and starts passing traffic. You can configure a redundant interface to increase the adaptive security appliance reliability. This feature is separate from device-level failover, but you can configure redundant interfaces as well as failover if desired.

This section describes how to configure redundant interfaces and includes the following topics:

- [Configuring a Redundant Interface, page 6-11](#)
- [Changing the Active Interface, page 6-14](#)

## Configuring a Redundant Interface

This section describes how to create a redundant interface. By default, redundant interfaces are enabled.

## Guidelines and Limitations

- You can configure up to 8 redundant interface pairs.
- All adaptive security appliance configuration refers to the logical redundant interface instead of the member physical interfaces.
- Redundant interface delay values are configurable, but by default the adaptive security appliance will inherit the default delay values based on the physical type of its member interfaces.
- The only configuration available to physical interfaces that are part of a redundant interface pair are physical parameters (set in the [“Enabling the Physical Interface and Configuring Ethernet Parameters” section on page 6-9](#)), the **description** command, and the **shutdown** command. You can also enter run-time commands like **default** and **help**.
- If you shut down the active interface, then the standby interface becomes active.

For failover, follow these guidelines when adding member interfaces:

- If you want to use a redundant interface for the failover or state link, then you must configure the redundant interface as part of the basic configuration on the secondary unit in addition to the primary unit.
- If you use a redundant interface for the failover or state link, you must put a switch or hub between the two units; you cannot connect them directly. Without the switch or hub, you could have the active port on the primary unit connected directly to the standby port on the secondary unit.
- You can monitor redundant interfaces for failover using the **monitor-interface** command; be sure to reference the logical redundant interface name.
- When the active interface fails over to the standby interface, this activity does not cause the redundant interface to appear to be failed when being monitored for device-level failover. Only when both physical interfaces fail does the redundant interface appear to be failed.

## Redundant Interface MAC Address

The redundant interface uses the MAC address of the first physical interface that you add. If you change the order of the member interfaces in the configuration, then the MAC address changes to match the MAC address of the interface that is now listed first. Alternatively, you can assign a MAC address to the redundant interface, which is used regardless of the member interface MAC addresses (see the [“Configuring the MAC Address” section on page 6-26](#) or the [“Assigning Interfaces to Contexts and Automatically Assigning MAC Addresses \(Multiple Context Mode\)” section on page 6-15](#)). When the active interface fails over to the standby, the same MAC address is maintained so that traffic is not disrupted.

## Prerequisites

- Both member interfaces must be of the same physical type. For example, both must be Ethernet.
- You cannot add a physical interface to the redundant interface if you configured a name for it. You must first remove the name using the **no nameif** command.
- For multiple context mode, complete this procedure in the system execution space. To change from the context to the system execution space, enter the **changeto system** command.

### Caution

If you are using a physical interface already in your configuration, removing the name will clear any configuration that refers to the interface.

## Detailed Steps

You can configure up to 8 redundant interface pairs. To configure a redundant interface, perform the following steps:

---

**Step 1** To add the logical redundant interface, enter the following command:

```
hostname(config)# interface redundant number
hostname(config-if)#
```

where the *number* argument is an integer between 1 and 8.

**Step 2** To add the first member interface to the redundant interface, enter the following command:

```
hostname(config-if)# member-interface physical_interface
```

See the [“Enabling the Physical Interface and Configuring Ethernet Parameters”](#) section for a description of the physical interface ID.

After you add the interface, any configuration for it (such as an IP address) is removed.

**Step 3** To add the second member interface to the redundant interface, enter the following command:

```
hostname(config-if)# member-interface physical_interface
```

Make sure the second interface is the same physical type as the first interface.

To remove a member interface, enter the **no member-interface** *physical\_interface* command. You cannot remove both member interfaces from the redundant interface; the redundant interface requires at least one member interface.

---

## Examples

The following example creates two redundant interfaces:

```
hostname(config)# interface redundant 1
hostname(config-if)# member-interface gigabitethernet 0/0
hostname(config-if)# member-interface gigabitethernet 0/1
hostname(config-if)# interface redundant 2
hostname(config-if)# member-interface gigabitethernet 0/2
hostname(config-if)# member-interface gigabitethernet 0/3
```

## What to Do Next

Optional Task:

- Configure VLAN subinterfaces. See the [“Configuring VLAN Subinterfaces and 802.1Q Trunking”](#) section on page 6-14.

Required Tasks:

- For multiple context mode, assign interfaces to contexts and automatically assign unique MAC addresses to context interfaces. See the [“Assigning Interfaces to Contexts and Automatically Assigning MAC Addresses \(Multiple Context Mode\)”](#) section on page 6-15.
- For single context mode, complete the interface configuration. See the [“Completing Interface Configuration \(All Models\)”](#) section on page 6-22.

## Changing the Active Interface

By default, the active interface is the first interface listed in the configuration, if it is available. To view which interface is active, enter the following command:

```
hostname# show interface redundantnumber detail | grep Member
```

For example:

```
hostname# show interface redundant1 detail | grep Member
Members GigabitEthernet0/3 (Active), GigabitEthernet0/2
```

To change the active interface, enter the following command:

```
hostname# redundant-interface redundantnumber active-member physical_interface
```

where the **redundantnumber** argument is the redundant interface ID, such as **redundant1**.

The *physical\_interface* is the member interface ID that you want to be active.

## Configuring VLAN Subinterfaces and 802.1Q Trunking

Subinterfaces let you divide a physical or redundant interface into multiple logical interfaces that are tagged with different VLAN IDs. An interface with one or more VLAN subinterfaces is automatically configured as an 802.1Q trunk. Because VLANs allow you to keep traffic separate on a given physical interface, you can increase the number of interfaces available to your network without adding additional physical interfaces or adaptive security appliances. This feature is particularly useful in multiple context mode so that you can assign unique interfaces to each context.

### Guidelines and Limitations

- Maximum subinterfaces—To determine how many VLAN subinterfaces are allowed for your platform, see the [“Licensing Requirements for Interfaces” section on page 6-6](#).
- Preventing untagged packets on the physical interface—If you use subinterfaces, you typically do not also want the physical interface to pass traffic, because the physical interface passes untagged packets. This property is also true for the active physical interface in a redundant interface pair. Because the physical or redundant interface must be enabled for the subinterface to pass traffic, ensure that the physical or redundant interface does not pass traffic by leaving out the **nameif** command. If you want to let the physical or redundant interface pass untagged packets, you can configure the **nameif** command as usual. See the [“Completing Interface Configuration \(All Models\)” section on page 6-22](#) for more information about completing the interface configuration.

### Prerequisites

For multiple context mode, complete this procedure in the system execution space. To change from the context to the system execution space, enter the **changeto system** command.

### Detailed Steps

To add a subinterface and assign a VLAN to it, perform the following steps:

- 
- Step 1** To specify the new subinterface, enter the following command:

```
hostname(config)# interface {physical_interface | redundant number}.subinterface
hostname(config-subif)#
```

See the [“Enabling the Physical Interface and Configuring Ethernet Parameters”](#) section for a description of the physical interface ID.

The **redundant number** argument is the redundant interface ID, such as **redundant 1**.

The *subinterface* ID is an integer between 1 and 4294967293.

The following command adds a subinterface to a Gigabit Ethernet interface:

```
hostname(config)# interface gigabitethernet 0/1.100
```

The following command adds a subinterface to a redundant interface:

```
hostname(config)# interface redundant 1.100
```

**Step 2** To specify the VLAN for the subinterface, enter the following command:

```
hostname(config-subif)# vlan vlan_id
```

The *vlan\_id* is an integer between 1 and 4094. Some VLAN IDs might be reserved on connected switches, so check the switch documentation for more information.

You can only assign a single VLAN to a subinterface, and you cannot assign the same VLAN to multiple subinterfaces. You cannot assign a VLAN to the physical interface. Each subinterface must have a VLAN ID before it can pass traffic. To change a VLAN ID, you do not need to remove the old VLAN ID with the **no** option; you can enter the **vlan** command with a different VLAN ID, and the adaptive security appliance changes the old ID.

## What to Do Next

- For multiple context mode, assign interfaces to contexts and automatically assign unique MAC addresses to context interfaces. See the [“Assigning Interfaces to Contexts and Automatically Assigning MAC Addresses \(Multiple Context Mode\)”](#) section on page 6-15.
- For single context mode, complete the interface configuration. See the [“Completing Interface Configuration \(All Models\)”](#) section on page 6-22.

## Assigning Interfaces to Contexts and Automatically Assigning MAC Addresses (Multiple Context Mode)

To complete the configuration of interfaces in the system execution space, perform the following tasks that are documented in [Chapter 5, “Configuring Multiple Context Mode”](#):

- To assign interfaces to contexts, see the [“Configuring a Security Context”](#) section on page 5-17.
- (Optional) To automatically assign unique MAC addresses to context interfaces, see the [“Automatically Assigning MAC Addresses to Context Interfaces”](#) section on page 5-22.

The MAC address is used to classify packets within a context. If you share an interface, but do not have unique MAC addresses for the interface in each context, then the destination IP address is used to classify packets. Alternatively, you can manually assign MAC addresses within the context according to the [“Configuring the MAC Address”](#) section on page 6-26.

## What to Do Next

Complete the interface configuration. See the [“Completing Interface Configuration \(All Models\)” section on page 6-22](#).

# Starting Interface Configuration (ASA 5505)

This section includes tasks for starting your interface configuration for the ASA 5505 adaptive security appliance, including creating VLAN interfaces and assigning them to switch ports. See the [“Understanding ASA 5505 Ports and Interfaces” section on page 6-2](#) for more information.

For ASA 5510 and higher configuration, see the [“Starting Interface Configuration \(ASA 5510 and Higher\)” section on page 6-8](#).

This section includes the following topics:

- [Task Flow for Starting Interface Configuration, page 6-16](#)
- [Configuring VLAN Interfaces, page 6-16](#)
- [Configuring and Enabling Switch Ports as Access Ports, page 6-17](#)
- [Configuring and Enabling Switch Ports as Trunk Ports, page 6-20](#)

## Task Flow for Starting Interface Configuration

To configure interfaces in single mode, perform the following steps:

- 
- |               |                                                                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Configure VLAN interfaces. See the <a href="#">“Configuring VLAN Interfaces” section on page 6-16</a> .                                                                                       |
| <b>Step 2</b> | Configure and enable switch ports as access ports. See the <a href="#">“Configuring and Enabling Switch Ports as Access Ports” section on page 6-17</a> .                                     |
| <b>Step 3</b> | (Optional for Security Plus licenses) Configure and enable switch ports as trunk ports. See the <a href="#">“Configuring and Enabling Switch Ports as Trunk Ports” section on page 6-20</a> . |
| <b>Step 4</b> | Complete the interface configuration according to the <a href="#">“Completing Interface Configuration (All Models)” section on page 6-22</a> .                                                |
- 

## Configuring VLAN Interfaces

This section describes how to configure VLAN interfaces. For more information about ASA 5505 interfaces, see the [“ASA 5505 Interfaces” section on page 6-2](#).

### Detailed Steps

- 
- |               |                                                       |
|---------------|-------------------------------------------------------|
| <b>Step 1</b> | To add a VLAN interface, enter the following command: |
|---------------|-------------------------------------------------------|

```
hostname(config)# interface vlan number
```

Where the *number* is between 1 and 4090.

For example, enter the following command:

```
hostname(config)# interface vlan 100
```

To remove this VLAN interface and all associated configuration, enter the **no interface vlan** command. Because this interface also includes the interface name configuration, and the name is used in other commands, those commands are also removed.

- Step 2** (Optional for the Base license) To allow this interface to be the third VLAN by limiting it from initiating contact to one other VLAN, enter the following command:

```
hostname(config-if)# no forward interface vlan number
```

Where *number* specifies the VLAN ID to which this VLAN interface cannot initiate traffic.

With the Base license, you can only configure a third VLAN if you use this command to limit it.

For example, you have one VLAN assigned to the outside for Internet access, one VLAN assigned to an inside business network, and a third VLAN assigned to your home network. The home network does not need to access the business network, so you can use the **no forward interface** command on the home VLAN; the business network can access the home network, but the home network cannot access the business network.

If you already have two VLAN interfaces configured with a **nameif** command, be sure to enter the **no forward interface** command before the **nameif** command on the third interface; the adaptive security appliance does not allow three fully functioning VLAN interfaces with the Base license on the ASA 5505 adaptive security appliance.

**Note**

If you upgrade to the Security Plus license, you can remove this command and achieve full functionality for this interface. If you leave this command in place, this interface continues to be limited even after upgrading.

## What to Do Next

Configure the switch ports. See the [“Configuring and Enabling Switch Ports as Access Ports”](#) section on page 6-17 and the [“Configuring and Enabling Switch Ports as Trunk Ports”](#) section on page 6-20.

## Configuring and Enabling Switch Ports as Access Ports

By default (with no configuration), all switch ports are shut down, and assigned to VLAN 1. To assign a switch port to a single VLAN, configure it as an access port. To create a trunk port to carry multiple VLANs, see the [“Configuring and Enabling Switch Ports as Trunk Ports”](#) section on page 6-20. If you have a factory default configuration, see the [“ASA 5505 Default Configuration”](#) section on page 2-2 to check if you want to change the default interface settings according to this procedure.

For more information about ASA 5505 interfaces, see the [“ASA 5505 Interfaces”](#) section on page 6-2.

**Caution**

The ASA 5505 adaptive security appliance does not support Spanning Tree Protocol for loop detection in the network. Therefore you must ensure that any connection with the adaptive security appliance does not end up in a network loop.

## Detailed Steps

- Step 1** To specify the switch port you want to configure, enter the following command:

```
hostname(config)# interface ethernet0/port
```

Where *port* is 0 through 7. For example, enter the following command:

```
hostname(config)# interface ethernet0/1
```

- Step 2** To assign this switch port to a VLAN, enter the following command:

```
hostname(config-if)# switchport access vlan number
```

Where *number* is the VLAN ID, between 1 and 4090. See the [“Configuring VLAN Interfaces” section on page 6-16](#) to configure the VLAN interface that you want to assign to this switch port. To view configured VLANs,

**Note** You might assign multiple switch ports to the primary or backup VLANs if the Internet access device includes Layer 2 redundancy.

- Step 3** (Optional) To prevent the switch port from communicating with other protected switch ports on the same VLAN, enter the following command:

```
hostname(config-if)# switchport protected
```

You might want to prevent switch ports from communicating with each other if the devices on those switch ports are primarily accessed from other VLANs, you do not need to allow intra-VLAN access, and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you apply the **switchport protected** command to each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

- Step 4** (Optional) To set the speed, enter the following command:

```
hostname(config-if)# speed {auto | 10 | 100}
```

The **auto** setting is the default. If you set the speed to anything other than **auto** on PoE ports Ethernet 0/6 or 0/7, then Cisco IP phones and Cisco wireless access points that do not support IEEE 802.3af will not be detected and supplied with power.

- Step 5** (Optional) To set the duplex, enter the following command:

```
hostname(config-if)# duplex {auto | full | half}
```

The **auto** setting is the default. If you set the duplex to anything other than **auto** on PoE ports Ethernet 0/6 or 0/7, then Cisco IP phones and Cisco wireless access points that do not support IEEE 802.3af will not be detected and supplied with power.

- Step 6** To enable the switch port, enter the following command:

```
hostname(config-if)# no shutdown
```

To disable the switch port, enter the **shutdown** command.

## Examples

The following example configures five VLAN interfaces, including the failover interface which is configured using the **failover lan** command:

```
hostname(config)# interface vlan 100
hostname(config-if)# nameif outside
hostname(config-if)# security-level 0
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 200
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.2.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 300
hostname(config-if)# nameif dmz
hostname(config-if)# security-level 50
hostname(config-if)# ip address 10.3.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 400
hostname(config-if)# nameif backup-isp
hostname(config-if)# security-level 50
hostname(config-if)# ip address 10.1.2.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# failover lan faillink vlan500
hostname(config)# failover interface ip faillink 10.4.1.1 255.255.255.0 standby 10.4.1.2
255.255.255.0

hostname(config)# interface ethernet 0/0
hostname(config-if)# switchport access vlan 100
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/1
hostname(config-if)# switchport access vlan 200
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/2
hostname(config-if)# switchport access vlan 300
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/3
hostname(config-if)# switchport access vlan 400
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/4
hostname(config-if)# switchport access vlan 500
hostname(config-if)# no shutdown
```

## What to Do Next

If you want to configure a switch port as a trunk port, see the [“Configuring and Enabling Switch Ports as Trunk Ports”](#) section on page 6-20.

To complete the interface configuration, see the [“Completing Interface Configuration \(All Models\)”](#) section on page 6-22.

## Configuring and Enabling Switch Ports as Trunk Ports

This procedure describes how to create a trunk port that can carry multiple VLANs using 802.1Q tagging. Trunk mode is available only with the Security Plus license.

To create an access port, where an interface is assigned to only one VLAN, see the [“Configuring and Enabling Switch Ports as Access Ports”](#) section on page 6-17.

For more information about ASA 5505 interfaces, see the [“ASA 5505 Interfaces”](#) section on page 6-2.

### Detailed Steps

- Step 1** To specify the switch port you want to configure, enter the following command:

```
hostname(config)# interface ethernet0/port
```

Where *port* is 0 through 7. For example, enter the following command:

```
hostname(config)# interface ethernet0/1
```

- Step 2** To assign VLANs to this trunk, enter one or more of the following commands.

- To assign native VLANs, enter the following command:

```
hostname(config-if)# switchport trunk native vlan vlan_id
```

where the *vlan\_id* is a single VLAN ID between 1 and 4090.

Packets on the native VLAN are not modified when sent over the trunk. For example, if a port has VLANs 2, 3 and 4 assigned to it, and VLAN 2 is the native VLAN, then packets on VLAN 2 that egress the port are not modified with an 802.1Q header. Frames which ingress (enter) this port and have no 802.1Q header are put into VLAN 2.

Each port can only have one native VLAN, but every port can have either the same or a different native VLAN.

- To assign VLANs, enter the following command:

```
hostname(config-if)# switchport trunk allowed vlan vlan_range
```

where the *vlan\_range* (with VLANs between 1 and 4090) can be identified in one of the following ways:

A single number (n)

A range (n-x)

Separate numbers and ranges by commas, for example:

5,7-10,13,45-100

You can enter spaces instead of commas, but the command is saved to the configuration with commas.

You can include the native VLAN in this command, but it is not required; the native VLAN is passed whether it is included in this command or not.

This switch port cannot pass traffic until you assign at least one VLAN to it, native or non-native.

- Step 3** To make this switch port a trunk port, enter the following command:

```
hostname(config-if)# switchport mode trunk
```

To restore this port to access mode, enter the **switchport mode access** command.

- Step 4** (Optional) To prevent the switch port from communicating with other protected switch ports on the same VLAN, enter the following command:

```
hostname(config-if)# switchport protected
```

You might want to prevent switch ports from communicating with each other if the devices on those switch ports are primarily accessed from other VLANs, you do not need to allow intra-VLAN access, and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you apply the **switchport protected** command to each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

- Step 5** (Optional) To set the speed, enter the following command:

```
hostname(config-if)# speed {auto | 10 | 100}
```

The **auto** setting is the default.

- Step 6** (Optional) To set the duplex, enter the following command:

```
hostname(config-if)# duplex {auto | full | half}
```

The **auto** setting is the default.

- Step 7** To enable the switch port, enter the following command:

```
hostname(config-if)# no shutdown
```

To disable the switch port, enter the **shutdown** command.

---

## Examples

The following example configures seven VLAN interfaces, including the failover interface which is configured using the **failover lan** command. VLANs 200, 201, and 202 are trunked on Ethernet 0/1.

```
hostname(config)# interface vlan 100
hostname(config-if)# nameif outside
hostname(config-if)# security-level 0
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 200
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.2.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 201
hostname(config-if)# nameif dept1
hostname(config-if)# security-level 90
hostname(config-if)# ip address 10.2.2.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 202
hostname(config-if)# nameif dept2
hostname(config-if)# security-level 90
hostname(config-if)# ip address 10.2.3.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 300
hostname(config-if)# nameif dmz
```

```

hostname(config-if)# security-level 50
hostname(config-if)# ip address 10.3.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 400
hostname(config-if)# nameif backup-isp
hostname(config-if)# security-level 50
hostname(config-if)# ip address 10.1.2.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# failover lan faillink vlan500
hostname(config)# failover interface ip faillink 10.4.1.1 255.255.255.0 standby 10.4.1.2
255.255.255.0

hostname(config)# interface ethernet 0/0
hostname(config-if)# switchport access vlan 100
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/1
hostname(config-if)# switchport mode trunk
hostname(config-if)# switchport trunk allowed vlan 200-202
hostname(config-if)# switchport trunk native vlan 5
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/2
hostname(config-if)# switchport access vlan 300
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/3
hostname(config-if)# switchport access vlan 400
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/4
hostname(config-if)# switchport access vlan 500
hostname(config-if)# no shutdown

```

## What to Do Next

To complete the interface configuration, see the [“Completing Interface Configuration \(All Models\)” section on page 6-22](#).

# Completing Interface Configuration (All Models)

This section includes tasks to complete the interface configuration for all models.

### Note

For multiple context mode, complete the tasks in this section in the context execution space. Enter the **changeto context *name*** command to change to the context you want to configure.

This section includes the following topics:

- [Entering Interface Configuration Mode, page 6-23](#)
- [Configuring General Interface Parameters, page 6-24](#)
- [Configuring the MAC Address, page 6-26](#)
- [Configuring IPv6 Addressing, page 6-27](#)

## Task Flow for Completing Interface Configuration

- 
- Step 1** Complete the procedures in the [“Starting Interface Configuration \(ASA 5510 and Higher\)”](#) section on page 6-8 or the [“Starting Interface Configuration \(ASA 5505\)”](#) section on page 6-16.
- Step 2** (Multiple context mode) Enter the **changeto context name** command to change to the context you want to configure.
- Step 3** Enter interface configuration mode. See the [“Entering Interface Configuration Mode”](#) section on page 6-23.
- Step 4** Configure general interface parameters, including the interface name, security level, and IPv4 address. See the [“Configuring General Interface Parameters”](#) section on page 6-24.
- For transparent mode, you do not configure IP addressing per interface, except for the management-only interface (see the [“Information About the Management Interface”](#) section on page 6-24). You do need to configure the other parameters in this section, however. To set the global management address for transparent mode, see the [“Configuring the IPv4 Address”](#) section on page 7-14.
- Step 5** (Optional) Configure the MAC address. See the [“Configuring the MAC Address”](#) section on page 6-26.
- Step 6** (Optional) Configure IPv6 addressing. See the [“Configuring IPv6 Addressing”](#) section on page 6-27.
- For transparent mode, you do not configure IP addressing per interface, except for the management-only interface (see the [“Information About the Management Interface”](#) section on page 6-24). To set the global management address for transparent mode, see the [“Configuring the IPv6 Address”](#) section on page 7-14.
- 

## Entering Interface Configuration Mode

The procedures in this section are performed in interface configuration mode.

### Prerequisites

For multiple context mode, complete this procedure in the context execution space. Enter the **changeto context name** command to change to the context you want to configure.

### Detailed Steps

If you are not already in interface configuration mode, enter the mode by using the **interface** command.

- For the ASA 5510 and higher:

```
hostname(config)# interface {{redundant number | physical_interface} [.subinterface] |  
mapped_name}  
hostname(config-if)#
```

The **redundant number** argument is the redundant interface ID, such as **redundant 1**.

See the [“Enabling the Physical Interface and Configuring Ethernet Parameters”](#) section for a description of the physical interface ID.

Append the *subinterface* ID to the physical or redundant interface ID separated by a period (.).

In multiple context mode, enter the *mapped\_name* if one was assigned using the **allocate-interface** command.

- For the ASA 5505:

```
hostname(config)# interface vlan number
hostname(config-if)#
```

## Configuring General Interface Parameters

This procedure describes how to set the name, security level, IPv4 address and other options.

For the ASA 5510 and higher, you must configure interface parameters for the following interface types:

- Physical interfaces
- VLAN subinterfaces
- Redundant interfaces

For the ASA 5505, you must configure interface parameters for the following interface types:

- VLAN interfaces

### Guidelines and Limitations

- For the ASA 5550 adaptive security appliance, for maximum throughput, be sure to balance your traffic over the two interface slots; for example, assign the inside interface to slot 1 and the outside interface to slot 0.
- For information about security levels, see the [“Security Levels” section on page 6-5](#).
- If you are using failover, do not use this procedure to name interfaces that you are reserving for failover and Stateful Failover communications. See the [“Configuring Active/Standby Failover” section on page 59-7](#) or the [“Configuring Active/Active Failover” section on page 58-8](#) to configure the failover and state links.
- In routed firewall mode, set the IP address for all interfaces.
- In transparent firewall mode, do not set the IP address for each interface, but rather set it for the whole adaptive security appliance or context. The exception is for the Management 0/0 or 0/1 management-only interface, which does not pass through traffic. To set the transparent firewall mode whole adaptive security appliance or context management IP address, see the [“Setting the Management IP Address for a Transparent Firewall” section on page 7-12](#). To set the IP address of the Management 0/0 or 0/1 interface or subinterface, use this procedure.

### Restrictions

PPPoE is not supported in multiple context mode or transparent firewall mode.

### Information About the Management Interface

The ASA 5510 and higher adaptive security appliance includes a dedicated management interface called Management 0/0 or Management 0/1, depending on your model, which is meant to support traffic to the adaptive security appliance. However, you can configure any interface to be a management-only interface. Also, for Management 0/0 or 0/1, you can disable management-only mode so the interface can pass through traffic just like any other interface.

Transparent firewall mode allows only two interfaces to pass through traffic; however, on the ASA 5510 and higher adaptive security appliance, you can use the Management 0/0 or 0/1 interface (either the physical interface or a subinterface) as a third interface for management traffic. The mode is not configurable in this case and must always be management-only.

## Prerequisites

- Complete the procedures in the [“Starting Interface Configuration \(ASA 5510 and Higher\)”](#) section on page 6-8 or the [“Starting Interface Configuration \(ASA 5505\)”](#) section on page 6-16.
- In multiple context mode, complete this procedure in the context execution space. To change from the system to a context configuration, enter the **changeto context** *name* command.
- Enter interface configuration mode according to the [“Entering Interface Configuration Mode”](#) section on page 6-23.

## Detailed Steps

- Step 1** To name the interface, enter the following command:

```
hostname(config-if)# nameif name
```

The *name* is a text string up to 48 characters, and is not case-sensitive. You can change the name by reentering this command with a new value. Do not enter the **no** form, because that command causes all commands that refer to that name to be deleted.

- Step 2** To set the security level, enter the following command:

```
hostname(config-if)# security-level number
```

Where *number* is an integer between 0 (lowest) and 100 (highest).

- Step 3** To set the IP address, enter one of the following commands.

**Note** For use with failover, you must set the IP address and standby address manually; DHCP and PPPoE are not supported.

In transparent firewall mode, do not set the IP address for each interface, but rather set it for the whole adaptive security appliance or context. The exception is for the Management 0/0 or 0/1 management-only interface, which does not pass through traffic.

- To set the IP address manually, enter the following command:

```
hostname(config-if)# ip address ip_address [mask] [standby ip_address]
```

where the *ip\_address* and *mask* arguments set the interface IP address and subnet mask.

The **standby** *ip\_address* argument is used for failover. See the [“Configuring Active/Standby Failover”](#) section on page 59-7 or the [“Configuring Active/Active Failover”](#) section on page 58-8 for more information.

- To obtain an IP address from a DHCP server, enter the following command:

```
hostname(config-if)# ip address dhcp [setroute]
```

where the **setroute** keyword lets the adaptive security appliance use the default route supplied by the DHCP server.

Reenter this command to reset the DHCP lease and request a new lease.

If you do not enable the interface using the **no shutdown** command before you enter the **ip address dhcp** command, some DHCP requests might not be sent.

- To obtain an IP address from a PPPoE server, see [Chapter 68, “Configuring the PPPoE Client.”](#)

PPPoE is not supported in multiple context mode.

- Step 4** (Optional) To set an interface to management-only mode so that it does not pass through traffic, enter the following command:

```
hostname(config-if)# management-only
```

See the [“Information About the Management Interface”](#) section on page 6-24 for more information.

## What to Do Next

- (Optional) Configure the MAC address. See the [“Configuring the MAC Address”](#) section on page 6-26.
- (Optional) Configure IPv6 addressing. See the [“Configuring IPv6 Addressing”](#) section on page 6-27.

## Configuring the MAC Address

This section describes how to configure MAC addresses for interfaces.

### Information About MAC Addresses

By default, the physical interface uses the burned-in MAC address, and all subinterfaces of a physical interface use the same burned-in MAC address. A redundant interface uses the MAC address of the first physical interface that you add. If you change the order of the member interfaces in the configuration, then the MAC address changes to match the MAC address of the interface that is now listed first. If you assign a MAC address to the redundant interface using this command, then it is used regardless of the member interface MAC addresses.

In multiple context mode, if you share an interface between contexts, you can assign a unique MAC address to the interface in each context. This feature lets the adaptive security appliance easily classify packets into the appropriate context. Using a shared interface without unique MAC addresses is possible, but has some limitations. See the [“How the Security Appliance Classifies Packets”](#) section on page 5-3 for more information. You can assign each MAC address manually, or you can automatically generate MAC addresses for shared interfaces in contexts. See the [“Automatically Assigning MAC Addresses to Context Interfaces”](#) section on page 5-22 to automatically generate MAC addresses. If you automatically generate MAC addresses, you can use this procedure to override the generated address.

For single context mode, or for interfaces that are not shared in multiple context mode, you might want to assign unique MAC addresses to subinterfaces. For example, your service provider might perform access control based on the MAC address.

### Prerequisites

Enter interface configuration mode according to the [“Entering Interface Configuration Mode”](#) section on page 6-23.

## Detailed Steps

To assign a private MAC address to this interface, enter the following command:

```
hostname(config-if)# mac-address mac_address [standby mac_address]
```

The *mac\_address* is in H.H.H format, where H is a 16-bit hexadecimal digit. For example, the MAC address 00-0C-F1-42-4C-DE is entered as 000C.F142.4CDE.

The first two bytes of a manual MAC address cannot be A2 if you also want to use auto-generated MAC addresses.

For use with failover, set the **standby** MAC address. If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.

## What to Do Next

(Optional) Configure IPv6 addressing. See the [“Configuring IPv6 Addressing” section on page 6-27](#).

# Configuring IPv6 Addressing

This section describes how to configure IPv6 addressing. For more information about IPv6, see the [“Information About IPv6 Support” section on page 19-9](#) and the [“IPv6 Addresses” section on page B-5](#).

For transparent mode, use this section for the Management 0/0 or 0/1 interface. To configure the global IPv6 management address for transparent mode, see the [“Configuring the IPv6 Address” section on page 7-14](#).

## Information About IPv6 Addressing

When you configure an IPv6 address on an interface, you can assign one or several IPv6 addresses to the interface at one time, such as an IPv6 link-local address and a global address. However, at a minimum, you must configure a link-local address.

Every IPv6-enabled interface must include at least one link-local address. When you configure a global address, a link-local addresses is automatically configured on the interface, so you do not also need to specifically configure a link-local address. These link-local addresses can only be used to communicate with other hosts on the same physical link.

### Note

If you want to only configure the link-local addresses, see the **ipv6 enable** (to auto-configure) or **ipv6 address link-local** (to manually configure) command in the *Cisco ASA 5500 Series Command Reference*.

When IPv6 is used over Ethernet networks, the Ethernet MAC address can be used to generate the 64-bit interface ID for the host. This is called the EUI-64 address. Because MAC addresses use 48 bits, additional bits must be inserted to fill the 64 bits required. The last 64 bits are used for the interface ID. For example, FE80::/10 is a link-local unicast IPv6 address type in hexadecimal format.

## Information About Duplicate Address Detection

During the stateless autoconfiguration process, duplicate address detection (DAD) verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces (the new addresses remain in a tentative state while duplicate address detection is performed). Duplicate address

detection is performed first on the new link-local address. When the link local address is verified as unique, then duplicate address detection is performed all the other IPv6 unicast addresses on the interface.

Duplicate address detection is suspended on interfaces that are administratively down. While an interface is administratively down, the unicast IPv6 addresses assigned to the interface are set to a pending state. An interface returning to an administratively up state restarts duplicate address detection for all of the unicast IPv6 addresses on the interface.

When a duplicate address is identified, the state of the address is set to DUPLICATE, the address is not used, and the following error message is generated:

```
%ASA-4-325002: Duplicate address ipv6_address/MAC_address on interface
```

If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface. If the duplicate address is a global address, the address is not used. However, all configuration commands associated with the duplicate address remain as configured while the state of the address is set to DUPLICATE.

If the link-local address for an interface changes, duplicate address detection is performed on the new link-local address and all of the other IPv6 address associated with the interface are regenerated (duplicate address detection is performed only on the new link-local address).

The adaptive security appliance uses neighbor solicitation messages to perform duplicate address detection. By default, the number of times an interface performs duplicate address detection is 1.

### Information About Modified EUI-64 Interface IDs

RFC 3513: Internet Protocol Version 6 (IPv6) Addressing Architecture requires that the interface identifier portion of all unicast IPv6 addresses, except those that start with binary value 000, be 64 bits long and be constructed in Modified EUI-64 format. The adaptive security appliance can enforce this requirement for hosts attached to the local link.

When this command is enabled on an interface, the source addresses of IPv6 packets received on that interface are verified against the source MAC addresses to ensure that the interface identifiers use the Modified EUI-64 format. If the IPv6 packets do not use the Modified EUI-64 format for the interface identifier, the packets are dropped and the following system log message is generated:

```
%ASA-3-325003: EUI-64 source address check failed.
```

The address format verification is only performed when a flow is created. Packets from an existing flow are not checked. Additionally, the address verification can only be performed for hosts on the local link. Packets received from hosts behind a router will fail the address format verification, and be dropped, because their source MAC address will be the router MAC address and not the host MAC address.

### Prerequisites

Enter interface configuration mode according to the [“Entering Interface Configuration Mode”](#) section on page 6-23.

### Restrictions

The adaptive security appliance does not support IPv6 anycast addresses.

## Detailed Steps

|        | Command                                                                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | Do one of the following:                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                |
|        | <b>ipv6 address autoconfig</b>                                                                                                                                                                                                        | Enables stateless autoconfiguration on the interface. Enabling stateless autoconfiguration on the interface configures IPv6 addresses based on prefixes received in Router Advertisement messages. A link-local address, based on the Modified EUI-64 interface ID, is automatically generated for the interface when stateless autoconfiguration is enabled.                                                                  |
|        | <b>Example:</b><br><pre>hostname(config-if)# ipv6 address autoconfig</pre><br><b>ipv6 address ipv6-prefix/prefix-length [eui-64]</b><br><br><b>Example:</b><br><pre>hostname(config-if)# ipv6 address 2001:0DB8::BA98:0:3210/48</pre> | Assigns a global address to the interface. When you assign a global address, the link-local address is automatically created for the interface. Use the optional <b>eui-64</b> keyword to use the Modified EUI-64 interface ID in the low order 64 bits of the address.<br><br>See the “IPv6 Addresses” section on page B-5 for more information about IPv6 addressing.                                                        |
| Step 2 | (Optional)<br><b>ipv6 nd suppress-ra</b>                                                                                                                                                                                              | Suppresses Router Advertisement messages on an interface. By default, Router Advertisement messages are automatically sent in response to router solicitation messages. You may want to disable these messages on any interface for which you do not want the adaptive security appliance to supply the IPv6 prefix (for example, the outside interface).                                                                      |
|        | <b>Example:</b><br><pre>hostname(config-if)# ipv6 nd suppress-ra</pre>                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Step 3 | (Optional)<br><b>ipv6 nd dad attempts value</b>                                                                                                                                                                                       | Changes the number of duplicate address detection attempts. The <i>value</i> argument can be any value from 0 to 600. Setting the <i>value</i> argument to 0 disables duplicate address detection on the interface.                                                                                                                                                                                                            |
|        | <b>Example:</b><br><pre>hostname(config-if)# ipv6 nd dad attempts 3</pre>                                                                                                                                                             | By default, the number of times an interface performs duplicate address detection is 1. See the “Information About Duplicate Address Detection” section on page 6-27 for more information.                                                                                                                                                                                                                                     |
| Step 4 | (Optional)<br><b>ipv6 nd ns-interval value</b>                                                                                                                                                                                        | Changes the neighbor solicitation message interval. When you configure an interface to send out more than one duplicate address detection attempt with the <b>ipv6 nd dad attempts</b> command, this command configures the interval at which the neighbor solicitation messages are sent out. By default, they are sent out once every 1000 milliseconds. The <i>value</i> argument can be from 1000 to 3600000 milliseconds. |
|        | <b>Example:</b><br><pre>hostname(config-if)# ipv6 nd ns-interval 2000</pre>                                                                                                                                                           | <b>Note</b> Changing this value changes it for all neighbor solicitation messages sent out on the interface, not just those used for duplicate address detection.                                                                                                                                                                                                                                                              |
| Step 5 | (Optional)<br><b>ipv6 enforce-eui64 if_name</b>                                                                                                                                                                                       | Enforces the use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link.                                                                                                                                                                                                                                                                                                                            |
|        | <b>Example:</b><br><pre>hostname(config)# ipv6 enforce-eui64 inside</pre>                                                                                                                                                             | The <i>if_name</i> argument is the name of the interface, as specified by the <b>nameif</b> command, on which you are enabling the address format enforcement.<br><br>See the “Information About Modified EUI-64 Interface IDs” section on page 6-28 for more information.                                                                                                                                                     |

# Allowing Same Security Level Communication

By default, interfaces on the same security level cannot communicate with each other, and packets cannot enter and exit the same interface. This section describes how to enable inter-interface communication when interfaces are on the same security level, and how to enable intra-interface communication.

## Information About Inter-Interface Communication

Allowing interfaces on the same security level to communicate with each other provides the following benefits:

- You can configure more than 101 communicating interfaces.  
If you use different levels for each interface and do not assign any interfaces to the same security level, you can configure only one interface per level (0 to 100).
- You want traffic to flow freely between all same security interfaces without access lists.

If you enable same security interface communication, you can still configure interfaces at different security levels as usual.

## Information About Intra-Interface Communication

Intra-interface communication might be useful for VPN traffic that enters an interface, but is then routed out the same interface. The VPN traffic might be unencrypted in this case, or it might be reencrypted for another VPN connection. For example, if you have a hub and spoke VPN network, where the security appliance is the hub, and remote VPN networks are spokes, for one spoke to communicate with another spoke, traffic must go into the security appliance and then out again to the other spoke.

### Note

All traffic allowed by this feature is still subject to firewall rules. Be careful not to create an asymmetric routing situation that can cause return traffic not to traverse the adaptive security appliance.

## Restrictions

This feature is only available in routed firewall mode.

## Detailed Steps

To enable interfaces on the same security level so that they can communicate with each other, enter the following command:

```
hostname(config)# same-security-traffic permit inter-interface
```

To enable communication between hosts connected to the same interface, enter the following command:

```
hostname(config)# same-security-traffic permit intra-interface
```

# Enabling Jumbo Frame Support (ASA 5580)

A jumbo frame is an Ethernet packet larger than the standard maximum of 1518 bytes (including Layer 2 header and FCS), up to 9216 bytes. You can enable support for jumbo frames for all interfaces by increasing the amount of memory to process Ethernet frames. Assigning more memory for jumbo frames might limit the maximum use of other features, such as access lists.

**Note**

Other platform models do not support jumbo frames.

## Prerequisites

In multiple context mode, set this option in the system execution space.

## Detailed Steps

To enable jumbo frame support for the ASA 5580 adaptive security appliance, enter the following command:

```
hostname(config)# jumbo-frame reservation
```

To disable jumbo frames, use the **no** form of this command.

**Note**

Changes in this setting require you to reboot the adaptive security appliance.

Be sure to set the MTU for each interface that needs to transmit jumbo frames to a higher value than the default 1500; for example, set the value to 9000 using the **mtu** command. See the [“Configuring the MAC Address” section on page 6-26](#). In multiple context mode, set the MTU within each context.

## Examples

The following example enables jumbo frame reservation, saves the configuration, and reloads the adaptive security appliance:

```
hostname(config)# jumbo-frame reservation
WARNING: this command will take effect after the running-config is saved
and the system has been rebooted. Command accepted.

hostname(config)# write memory
Building configuration...
Cryptochecksum: 718e3706 4edb11ea 69af58d0 0a6b7cb5

70291 bytes copied in 3.710 secs (23430 bytes/sec)
[OK]
hostname(config)# reload
Proceed with reload? [confirm] y
```

# Monitoring Interfaces

To monitor interfaces, enter one of the following commands:

| Command                              | Purpose                                     |
|--------------------------------------|---------------------------------------------|
| <code>show interface</code>          | Displays interface statistics.              |
| <code>show interface ip brief</code> | Displays interface IP addresses and status. |

## Configuration Examples for Interfaces

This section includes examples for interface configuration and includes the following topics:

- [Physical Interface Parameters Example, page 6-32](#)
- [Subinterface Parameters Example, page 6-32](#)
- [Multiple Context Mode Examples, page 6-32](#)
- [ASA 5505 Example, page 6-33](#)

### Physical Interface Parameters Example

The following example configures parameters for the physical interface in single mode:

```
hostname(config)# interface gigabitethernet 0/1
hostname(config-if)# speed 1000
hostname(config-if)# duplex full
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown
```

### Subinterface Parameters Example

The following example configures parameters for a subinterface in single mode:

```
hostname(config)# interface gigabitethernet 0/1.1
hostname(config-subif)# vlan 101
hostname(config-subif)# nameif dmz1
hostname(config-subif)# security-level 50
hostname(config-subif)# ip address 10.1.2.1 255.255.255.0
hostname(config-subif)# mac-address 000C.F142.4CDE standby 020C.F142.4CDE
hostname(config-subif)# no shutdown
```

### Multiple Context Mode Examples

The following example configures interface parameters in multiple context mode for the system configuration, and allocates the gigabitethernet 0/1.1 subinterface to contextA:

```
hostname(config)# interface gigabitethernet 0/1
```

```
hostname(config-if)# speed 1000
hostname(config-if)# duplex full
hostname(config-if)# no shutdown
hostname(config-if)# interface gigabitethernet 0/1.1
hostname(config-subif)# vlan 101
hostname(config-subif)# no shutdown
hostname(config-subif)# context contextA
hostname(config-ctx)# ...
hostname(config-ctx)# allocate-interface gigabitethernet 0/1.1
```

The following example configures parameters in multiple context mode for the context configuration:

```
hostname/contextA(config)# interface gigabitethernet 0/1.1
hostname/contextA(config-if)# nameif inside
hostname/contextA(config-if)# security-level 100
hostname/contextA(config-if)# ip address 10.1.2.1 255.255.255.0
hostname/contextA(config-if)# mac-address 030C.F142.4CDE standby 040C.F142.4CDE
hostname/contextA(config-if)# no shutdown
```

## ASA 5505 Example

The following example configures three VLAN interfaces for the Base license. The third home interface cannot forward traffic to the business interface.

```
hostname(config)# interface vlan 100
hostname(config-if)# nameif outside
hostname(config-if)# security-level 0
hostname(config-if)# ip address dhcp
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 200
hostname(config-if)# nameif business
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 300
hostname(config-if)# no forward interface vlan 200
hostname(config-if)# nameif home
hostname(config-if)# security-level 50
hostname(config-if)# ip address 10.2.1.1 255.255.255.0
hostname(config-if)# no shutdown
```

# Feature History for Interfaces

Table 6-1 lists the release history for this feature.

**Table 6-1** Feature History for Interfaces

| Feature Name                                                    | Releases      | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Increased VLANs                                                 | 7.0(5)        | Increased the following limits: <ul style="list-style-type: none"> <li>ASA5510 Base license VLANs from 0 to 10.</li> <li>ASA5510 Security Plus license VLANs from 10 to 25.</li> <li>ASA5520 VLANs from 25 to 100.</li> <li>ASA5540 VLANs from 100 to 200.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Increased interfaces for the Base license on the ASA 5510       | 7.2(2)        | For the Base license on the ASA 5510, the maximum number of interfaces was increased from 3 plus a management interface to unlimited interfaces.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Increased VLANs                                                 | 7.2(2)        | <p>The maximum number of VLANs for the Security Plus license on the ASA 5505 adaptive security appliance was increased from 5 (3 fully functional; 1 failover; one restricted to a backup interface) to 20 fully functional interfaces. In addition, the number of trunk ports was increased from 1 to 8. Now there are 20 fully functional interfaces, you do not need to use the backup interface command to cripple a backup ISP interface; you can use a fully-functional interface for it. The backup interface command is still useful for an Easy VPN configuration.</p> <p>VLAN limits were also increased for the ASA 5510 adaptive security appliance (from 10 to 50 for the Base license, and from 25 to 100 for the Security Plus license), the ASA 5520 adaptive security appliance (from 100 to 150), the ASA 5550 adaptive security appliance (from 200 to 250).</p> |
| Gigabit Ethernet Support for the ASA 5510 Security Plus License | 7.2(3)        | The ASA 5510 adaptive security appliance now supports GE (Gigabit Ethernet) for port 0 and 1 with the Security Plus license. If you upgrade the license from Base to Security Plus, the capacity of the external Ethernet0/0 and Ethernet0/1 ports increases from the original FE (Fast Ethernet) (100 Mbps) to GE (1000 Mbps). The interface names will remain Ethernet 0/0 and Ethernet 0/1. Use the <b>speed</b> command to change the speed on the interface and use the <b>show interface</b> command to see what speed is currently configured for each interface.                                                                                                                                                                                                                                                                                                            |
| Native VLAN support for the ASA 5505                            | 7.2(4)/8.0(4) | <p>You can now include the native VLAN in an ASA 5505 trunk port.</p> <p>The following command was introduced: <b>switchport trunk native vlan</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 6-1**      *Feature History for Interfaces (continued)*

| Feature Name                                                                             | Releases | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------------------------------------------------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Jumbo packet support for the ASA 5580                                                    | 8.1(1)   | <p>The Cisco ASA 5580 supports jumbo frames. A jumbo frame is an Ethernet packet larger than the standard maximum of 1518 bytes (including Layer 2 header and FCS), up to 9216 bytes. You can enable support for jumbo frames for all interfaces by increasing the amount of memory to process Ethernet frames. Assigning more memory for jumbo frames might limit the maximum use of other features, such as access lists.</p> <p>The following command was introduced: <b>jumbo-frame reservation</b>.</p> |
| Increased VLANs for the ASA 5580                                                         | 8.1(2)   | The number of VLANs supported on the ASA 5580 are increased from 100 to 250.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Support for Pause Frames for Flow Control on the ASA 5580 10 Gigabit Ethernet Interfaces | 8.2(2)   | <p>You can now enable pause (XOFF) frames for flow control.</p> <p>The following command was introduced: <b>flowcontrol</b>.</p>                                                                                                                                                                                                                                                                                                                                                                             |

# CHAPTER 7

## Configuring Basic Settings

This chapter describes how to configure basic settings on your adaptive security appliance that are typically required for a functioning configuration. This chapter includes the following sections:

- [Configuring the Hostname, Domain Name, and Passwords, page 7-1](#)
- [Setting the Date and Time, page 7-3](#)
- [Configuring the Master Passphrase, page 7-6](#)
- [Configuring the DNS Server, page 7-11](#)
- [Setting the Management IP Address for a Transparent Firewall, page 7-12](#)

## Configuring the Hostname, Domain Name, and Passwords

This section describes how to change the device name and passwords, and includes the following topics:

- [Changing the Login Password, page 7-1](#)
- [Changing the Enable Password, page 7-2](#)
- [Setting the Hostname, page 7-2](#)
- [Setting the Domain Name, page 7-3](#)

### Changing the Login Password

The login password is used for Telnet and SSH connections. By default, the login password is “cisco.” To change the password, enter the following command:

| Command                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{<b>passwd</b>   <b>password</b>} <i>password</i></code> | <p>Changes the password.</p> <p>You can enter <b>passwd</b> or <b>password</b>. The password is a case-sensitive password of up to 16 alphanumeric and special characters. You can use any character in the password except a question mark or a space.</p> <p>The password is saved in the configuration in encrypted form, so you cannot view the original password after you enter it. Use the <code>no password</code> command to restore the password to the default setting.</p> |

## Changing the Enable Password

The enable password lets you enter privileged EXEC mode. By default, the enable password is blank. To change the enable password, enter the following command:

| Command                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>enable password <i>password</i></code> | <p>Changes the enable password.</p> <p>The <i>password</i> is a case-sensitive password of up to 16 alphanumeric and special characters. You can use any character in the password except a question mark or a space.</p> <p>This command changes the password for the highest privilege level. If you configure local command authorization, you can set enable passwords for each privilege level from 0 to 15.</p> <p>The password is saved in the configuration in encrypted form, so you cannot view the original password after you enter it. Enter the <b>enable password</b> command without a password to set the password to the default, which is blank.</p> |

## Setting the Hostname

When you set a hostname for the adaptive security appliance, that name appears in the command line prompt. If you establish sessions to multiple devices, the hostname helps you keep track of where you enter commands. The default hostname depends on your platform.

For multiple context mode, the hostname that you set in the system execution space appears in the command line prompt for all contexts. The hostname that you optionally set within a context does not appear in the command line, but can be used by the **banner** command **\$(hostname)** token.

| Command                                                                                                                          | Purpose                                                                                                                                                                                                                                                   |
|----------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><code>hostname <i>name</i></code></p> <p><b>Example:</b></p> <pre>hostname(config)# hostname farscape farscape(config)#</pre> | <p>Specifies the hostname for the adaptive security appliance or for a context.</p> <p>This name can be up to 63 characters. A hostname must start and end with a letter or digit, and have as interior characters only letters, digits, or a hyphen.</p> |

## Setting the Domain Name

The adaptive security appliance appends the domain name as a suffix to unqualified names. For example, if you set the domain name to “example.com,” and specify a syslog server by the unqualified name of “jupiter,” then the security appliance qualifies the name to “jupiter.example.com.”

The default domain name is default.domain.invalid.

For multiple context mode, you can set the domain name for each context, as well as within the system execution space.

| Command                                                | Purpose                                                        |
|--------------------------------------------------------|----------------------------------------------------------------|
| <code>domain-name name</code>                          | Specifies the domain name for the adaptive security appliance. |
| <b>Example:</b>                                        | For example, to set the domain as example.com.                 |
| <code>hostname(config)# domain-name example.com</code> |                                                                |

## Setting the Date and Time

This section describes how to set the date and time, either manually or dynamically using an NTP server. Time derived from an NTP server overrides any time set manually. This section also describes how to set the time zone and daylight saving time date range.

**Note**

In multiple context mode, set the time in the system configuration only.

This section includes the following topics:

- [Setting the Time Zone and Daylight Saving Time Date Range, page 7-4](#)
- [Setting the Date and Time Using an NTP Server, page 7-5](#)
- [Setting the Date and Time Manually, page 7-6](#)

## Setting the Time Zone and Daylight Saving Time Date Range

By default, the time zone is UTC and the daylight saving time date range is from 2:00 a.m. on the first Sunday in April to 2:00 a.m. on the last Sunday in October. To change the time zone and daylight saving time date range, perform the following steps:

| Command                                                                                                                                                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b><br><code>clock timezone zone</code><br><code>[-]hours [minutes]</code>                                                                                                                                                                                             | <p>Sets the time zone.</p> <p>Where <i>zone</i> specifies the time zone as a string, for example, <b>PST</b> for Pacific Standard Time.</p> <p>The <code>[-]hours</code> value sets the number of hours of offset from UTC. For example, PST is <b>-8</b> hours.</p> <p>The <i>minutes</i> value sets the number of minutes of offset from UTC.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 2</b><br>Do one of the following to change the date range for daylight saving time from the default, enter one of the following commands. The default recurring date range is from 2:00 a.m. on the second Sunday in March to 2:00 a.m. on the first Sunday in November: |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>clock summer-time zone</code><br><code>date {day month   month</code><br><code>day} year hh:mm {day</code><br><code>month   month day} year</code><br><code>hh:mm [offset]</code>                                                                                          | <p>Sets the start and end dates for daylight saving time as a specific date in a specific year. If you use this command, you need to reset the dates every year.</p> <p>The <i>zone</i> value specifies the time zone as a string, for example, <b>PDT</b> for Pacific Daylight Time.</p> <p>The <i>day</i> value sets the day of the month, from 1 to 31. You can enter the day and month as <b>April 1</b> or as <b>1 April</b>, for example, depending on your standard date format.</p> <p>The <i>month</i> value sets the month as a string. You can enter the day and month as <b>April 1</b> or as <b>1 April</b>, for example, depending on your standard date format.</p> <p>The <i>year</i> value sets the year using four digits, for example, <b>2004</b>. The year range is 1993 to 2035.</p> <p>The <i>hh:mm</i> value sets the hour and minutes in 24-hour time.</p> <p>The <i>offset</i> value sets the number of minutes to change the time for daylight saving time. By default, the value is 60 minutes.</p> |
| <code>clock summer-time zone</code><br><code>recurring [week weekday</code><br><code>month hh:mm week weekday</code><br><code>month hh:mm] [offset]</code>                                                                                                                       | <p>Specifies the start and end dates for daylight saving time, in the form of a day and time of the month, and not a specific date in a year.</p> <p>This command lets you set a recurring date range that you do not need to alter yearly.</p> <p>The <i>zone</i> value specifies the time zone as a string, for example, <b>PDT</b> for Pacific Daylight Time.</p> <p>The <i>week</i> value specifies the week of the month as an integer between 1 and 4 or as the words <b>first</b> or <b>last</b>. For example, if the day might fall in the partial fifth week, then specify <b>last</b>.</p> <p>The <i>weekday</i> value specifies the day of the week: <b>Monday</b>, <b>Tuesday</b>, <b>Wednesday</b>, and so on.</p> <p>The <i>month</i> value sets the month as a string.</p> <p>The <i>hh:mm</i> value sets the hour and minutes in 24-hour time.</p> <p>The <i>offset</i> value sets the number of minutes to change the time for daylight saving time. By default, the value is 60 minutes.</p>                  |

## Setting the Date and Time Using an NTP Server

To obtain the date and time from an NTP server, perform the following steps.

### Detailed Steps

|        | Command                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|-----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>ntp authenticate</code>                                                                                               | Enables authentication with an NTP server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Step 2 | <code>ntp trusted-key <i>key_id</i></code>                                                                                  | Specifies an authentication key ID to be a trusted key, which is required for authentication with an NTP server.<br><br>Where the <i>key_id</i> is between 1 and 4294967295. You can enter multiple trusted keys for use with multiple servers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 3 | <code>ntp authentication-key <i>key_id</i><br/>md5 <i>key</i></code>                                                        | Sets a key to authenticate with an NTP server.<br><br>Where <i>key_id</i> is the ID you set in <a href="#">Step 2</a> using the <code>ntp trusted-key</code> command, and <i>key</i> is a string up to 32 characters in length.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 4 | <code>ntp server <i>ip_address</i> [<b>key</b><br/><i>key_id</i>] [<i>source interface_name</i>]<br/>[<b>prefer</b>]</code> | Identifies an NTP server.<br><br>Where the <i>key_id</i> is the ID you set in <a href="#">Step 2</a> using the <code>ntp trusted-key</code> command.<br><br>The <b>source interface_name</b> identifies the outgoing interface for NTP packets if you do not want to use the default interface in the routing table. Because the system does not include any interfaces in multiple context mode, specify an interface name defined in the admin context.<br><br>The <b>prefer</b> keyword sets this NTP server as the preferred server if multiple servers have similar accuracy. NTP uses an algorithm to determine which server is the most accurate and synchronizes to that one. If servers are of similar accuracy, then the <b>prefer</b> keyword specifies which of those servers to use. However, if a server is significantly more accurate than the preferred one, the adaptive security appliance uses the more accurate one. For example, the adaptive security appliance uses a server of stratum 2 over a server of stratum 3 that is preferred.<br><br>You can identify multiple servers; the adaptive security appliance uses the most accurate server. |

## Setting the Date and Time Manually

| Command                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>clock set hh:mm:ss {month day   day month} year</code> | <p>Sets the date time manually.</p> <p>Where <i>hh:mm:ss</i> sets the hour, minutes, and seconds in 24-hour time. For example, set <b>20:54:00</b> for 8:54 pm.</p> <p>The <i>day</i> value sets the day of the month, from 1 to 31. You can enter the day and month as <b>april 1</b> or as <b>1 april</b>, for example, depending on your standard date format.</p> <p>The <i>month</i> value sets the month. Depending on your standard date format, you can enter the day and month as <b>april 1</b> or as <b>1 april</b>.</p> <p>The <i>year</i> value sets the year using four digits, for example, <b>2004</b>. The year range is 1993 to 2035.</p> <p>The default time zone is UTC. If you change the time zone after you enter the <b>clock set</b> command using the <b>clock timezone</b> command, the time automatically adjusts to the new time zone.</p> <p>This command sets the time in the hardware chip, and does not save the time in the configuration file. This time endures reboots. Unlike the other <b>clock</b> commands, this command is a privileged EXEC command. To reset the clock, you need to set a new time for the <b>clock set</b> command.</p> |

## Configuring the Master Passphrase

This section describes how to configure the master passphrase. This section includes the following topics:

- [Information About the Master Passphrase, page 7-6](#)
- [Licensing Requirements for the Master Passphrase, page 7-7](#)
- [Guidelines and Limitations, page 7-7](#)
- [Adding or Changing the Master Passphrase, page 7-7](#)
- [Disabling the Master Passphrase, page 7-9](#)
- [Recovering the Master Passphrase, page 7-10](#)
- [Feature History for the Master Passphrase, page 7-11](#)

## Information About the Master Passphrase

The master passphrase feature allows you to securely store plain text passwords in encrypted format. The master passphrase provides a key that is used to universally encrypt or mask all passwords, without changing any functionality. Passwords that take advantage of this feature include:

- OSPF

- EIGRP
- VPN load balancing
- VPN (remote access and site-to-site)
- Failover
- AAA servers
- Logging
- Shared licenses
- And many more...

## Licensing Requirements for the Master Passphrase

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

## Adding or Changing the Master Passphrase

This section describes how to configure the master passphrase feature.

### Prerequisites

- If failover is enabled but no failover shared key is set, then changing the master passphrase displays an error message, informing you that a failover shared key must be entered to protect the master passphrase changes from being sent as plain text.
- This procedure will only be accepted in a secure session, for example by console, SSH or ASDM via HTTPS.

## Detailed Steps

|        | Command                                                                                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>key config-key password-encryption</b><br><code>[new_passphrase [old_passphrase]]</code><br><br><b>Example:</b><br><pre>hostname(config)# key config-key password-encryption Old key: bumblebee New key: haverford Confirm key: haverford</pre> | <p>Sets the passphrase used for generating the encryption key, between 8 and 128 characters in length. All characters except back space and double quote are accepted for the passphrase.</p> <p>If you do not enter the new passphrase in the command, you are prompted for it.</p> <p>When you want to change the passphrase, you also have to enter the old passphrase.</p> <p>See the “<a href="#">Examples</a>” section on page 7-9 for examples of the interactive prompts.</p> <p><b>Note</b> It is advised to use the interactive prompts to enter passwords, to avoid the passwords being logged in the command history buffer.</p> <p>Use the <b>no key config-key password-encrypt</b> command with caution as it will turn the encrypted passwords into plain text passwords. You can use the <b>no</b> form of this command when downgrading to a software version that does not support password encryption.</p> |
| Step 2 | <b>password encryption aes</b><br><br><b>Example:</b><br><pre>hostname(config)# password encryption aes</pre>                                                                                                                                      | <p>Enables password encryption. As soon as password encryption is turned on and master passphrase is available all the user passwords will be encrypted. The running configuration will show the passwords in the encrypted format.</p> <p>If the passphrase is not configured at the time of enabling password encryption, the command will succeed in anticipation that the passphrase will be available in future.</p> <p>If you later disable password encryption using the <b>no password encryption aes</b> command, all existing encrypted passwords are left unchanged, and as long as the master passphrase exists, the encrypted passwords will be decrypted as required by the application.</p>                                                                                                                                                                                                                     |
| Step 3 | <b>write memory</b><br><br><b>Example:</b><br><pre>hostname(config)# write memory</pre>                                                                                                                                                            | <p>Saves the run time value of the master passphrase and the resultant configuration. Unless that is done, passwords in startup configuration may still be visible if they were not saved with encryption before.</p> <p>Further, in multiple mode the master passphrase is changed in the system context configuration. As a result the passwords in all contexts will be affected. If the <b>write memory</b> command is not entered in the system context mode but not in all user contexts then the encrypted passwords in user contexts may be stale. Alternately, use the <b>write memory all</b> command in system context to save all configuration.</p>                                                                                                                                                                                                                                                               |

## Examples

In the following configuration example, no previous key is present:

```
hostname (config)# key config-key password-encryption 12345678
```

In the following configuration example, no previous key is present:

```
hostname (config)# key config-key password-encryption 12345678
```

In the following configuration example, a key already exists:

```
Hostname (config)# key config-key password-encryption 23456789  
Old key: 12345678  
hostname (config)#
```

In the following configuration example, the user wants to key in interactively, but a key already exists. The Old key, New key, and Confirm key prompts will appear on your screen if you enter the **key config-key password-encryption** command and press the enter key to get into interactive mode.

```
hostname (config)# key config-key password-encryption  
Old key: 12345678  
New key: 23456789  
Confirm key: 23456789
```

In the following example, the user wants to key in interactively, but no key is present. The New key and Confirm key prompts will appear on your screen if you are in interactive mode.

```
hostname (config)# key config-key password-encryption  
New key: 12345678  
Confirm key: 12345678
```

## Disabling the Master Passphrase

Disabling the master passphrase reverts encrypted passwords into plain text passwords. Removing the passphrase might be useful if you downgrade to a previous software version that does not support encrypted passwords.

### Prerequisites

- You must know the current master passphrase to disable it. If you do not know the passphrase, see the [“Recovering the Master Passphrase”](#) section on page 7-10.
- This procedure will only be accepted in a secure session, for example by console, SSH or ASDM via HTTPS.

## Detailed Steps

|        | Command                                                                                                                                                                                                                                                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p><b>no key config-key password-encryption</b><br/>[old_passphrase]]</p> <p><b>Example:</b><br/>hostname(config)# no key config-key password-encryption</p> <p>Warning! You have chosen to revert the encrypted passwords to plain text. This operation will expose passwords in the configuration and therefore exercise caution while viewing, storing, and copying configuration.</p> <p>Old key: bumblebee</p> | <p>Removes the master passphrase.</p> <p>If you do not enter the passphrase in the command, you are prompted for it.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 2 | <p><b>write memory</b></p> <p><b>Example:</b><br/>hostname(config)# write memory</p>                                                                                                                                                                                                                                                                                                                                | <p>Saves the run time value of the master passphrase and the resultant configuration. The non-volatile memory containing the passphrase will be erased and overwritten with 0xFF pattern.</p> <p>In multiple mode the master passphrase is changed in the system context configuration. As a result the passwords in all contexts will be affected. If the <b>write memory</b> command is not entered in the system context mode but not in all user contexts then the encrypted passwords in user contexts may be stale. Alternately, use the <b>write memory all</b> command in system context to save all configuration.</p> |

## Recovering the Master Passphrase

You cannot recover the master passphrase.

If the master passphrase is lost or unknown, it could be removed by using the **write erase** command followed by the **reload** command. This removes the master key along with the configuration containing the encrypted passwords.

## Feature History for the Master Passphrase

Table 7-2 lists each feature change and the platform release in which it was implemented.

**Table 1** Feature History for the Master Passphrase

| Feature Name      | Platform Releases | Feature Information                                                                                                                                                                                                                                            |
|-------------------|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Master Passphrase | 8.3(1)            | This feature was introduced.<br><br>The following commands were introduced: <b>key config-key password-encryption</b> , <b>password encryption aes</b> , <b>clear configure password encryption aes</b> , <b>show running-config password encryption aes</b> . |

## Configuring the DNS Server

Some adaptive security appliance features require use of a DNS server to access external servers by domain name; for example, the Botnet Traffic Filter feature requires a DNS server to access the dynamic database server and to resolve entries in the static database. Other features, such as the **ping** or **traceroute** command, let you enter a name that you want to PING for traceroute, and the adaptive security appliance can resolve the name by communicating with a DNS server. Many SSL VPN and certificate commands also support names.

### Note

The adaptive security appliance has limited support for using the DNS server, depending on the feature. For example, most commands require you to enter an IP address and can only use a name when you manually configure the **name** command to associate a name with an IP address and enable use of the names using the **names** command.

For information about dynamic DNS, see the “[Configuring DDNS](#)” section on page 9-2.

### Prerequisites

Make sure you configure the appropriate routing for any interface on which you enable DNS domain lookup so you can reach the DNS server. See the “[Information About Routing](#)” section on page 19-1 for more information about routing.

### Detailed Steps

|        | Command                                                                                                                | Purpose                                                                                                                       |
|--------|------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>dns domain-lookup</b> <i>interface_name</i><br><br><b>Example:</b><br>hostname(config)# dns domain-lookup<br>inside | Enables the adaptive security appliance to send DNS requests to a DNS server to perform a name lookup for supported commands. |

|        |                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                    |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 2 | <b>dns server-group DefaultDNS</b><br><br><b>Example:</b><br><pre>hostname(config)# dns server-group DefaultDNS</pre>                                                                   | <p>Specifies the DNS server group that the adaptive security appliance uses for from-the-box requests.</p> <p>Other DNS server groups can be configured for VPN tunnel groups. See the <b>tunnel-group</b> command in the <i>Cisco ASA 5500 Series Command Reference</i> for more information.</p> |
| Step 3 | <b>name-server ip_address [ip_address2] [...]</b> [ip_address6]<br><br><b>Example:</b><br><pre>hostname(config-dns-server-group)# name-server 10.1.1.5 192.168.1.67 209.165.201.6</pre> | <p>Specifies one or more DNS servers. You can enter all 6 IP addresses in the same command, separated by spaces, or you can enter each command separately. The security appliance tries each DNS server in order until it receives a response.</p>                                                 |

## Setting the Management IP Address for a Transparent Firewall

This section describes how to configure the management IP address for transparent firewall mode, and includes the following topics:

- [Information About the Management IP Address, page 7-12](#)
- [Licensing Requirements for the Management IP Address for a Transparent Firewall, page 7-13](#)
- [Guidelines and Limitations, page 7-13](#)
- [Configuring the IPv4 Address, page 7-14](#)
- [Configuring the IPv6 Address, page 7-14](#)
- [Configuration Examples for the Management IP Address for a Transparent Firewall, page 7-14](#)
- [Feature History for the Management IP Address for a Transparent Firewall, page 7-15](#)

## Information About the Management IP Address

A transparent firewall does not participate in IP routing. The only IP configuration required for the adaptive security appliance is to set the management IP address. This address is required because the adaptive security appliance uses this address as the source address for traffic originating on the adaptive security appliance, such as system messages or communications with AAA servers. You can also use this address for remote management access.

For IPv4 traffic, the management IP address is required to pass any traffic. For IPv6 traffic, you must, at a minimum, configure the link-local addresses to pass traffic, but a global management address is recommended for full functionality, including remote management and other management operations.

### Note

In addition to the management IP address for the device, you can configure an IP address for the Management 0/0 or 0/1 management-only interface. This IP address can be on a separate subnet from the main management IP address. See the [“Configuring General Interface Parameters”](#) section on [page 6-24](#).

Although you do not configure IPv4 or global IPv6 addresses for other interfaces, you still need to configure the security level and interface name according to the [“Configuring General Interface Parameters”](#) section on [page 6-24](#).

## Licensing Requirements for the Management IP Address for a Transparent Firewall

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode. For multiple context mode, set the management IP address within each context.

### Firewall Mode Guidelines

Supported in transparent firewall mode. For routed mode, set the IP address for each interface according to the [“Configuring General Interface Parameters” section on page 6-24](#).

### IPv6 Guidelines

- Supports IPv6.
- The following IPv6 address-related commands are not supported in transparent mode, because they require router capabilities:
  - **ipv6 address autoconfig**
  - **ipv6 nd suppress-ra**

For a complete list of IPv6 commands that are not supported in transparent mode, see the [“IPv6-Enabled Commands” section on page 19-10](#).

- No support for IPv6 anycast addresses.
- You can configure both IPv6 and IPv4 addresses.

### Additional Guidelines and Limitations

- In addition to the management IP address for the device, you can configure an IP address for the Management 0/0 or 0/1 management-only interface. This IP address can be on a separate subnet from the main management IP address. See the [“Configuring General Interface Parameters” section on page 6-24](#).
- Although you do not configure IP addresses for other interfaces, you still need to configure the security level and interface name according to the [“Configuring General Interface Parameters” section on page 6-24](#).

## Configuring the IPv4 Address

This section tells how to configure the IPv4 address.

### Detailed Steps

| Command                                                                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ip address</b> <i>ip_address</i> [ <i>mask</i> ]<br>[ <b>standby</b> <i>ip_address</i> ]<br><br><b>Example:</b><br>hostname(config)# ip address 10.1.1.1<br>255.255.255.0 standby 10.1.1.2 | This address must be on the same subnet as the upstream and downstream routers. You cannot set the subnet to a host subnet (255.255.255.255). The <b>standby</b> keyword and address is used for failover. See the <a href="#">“Configuring Active/Standby Failover”</a> section on page 59-7 or the <a href="#">“Configuring Active/Active Failover”</a> section on page 58-8 for more information. |

## Configuring the IPv6 Address

When you configure a global address, a link-local addresses is automatically configured on each interface, so you do not also need to specifically configure a link-local address.

### Note

If you want to only configure the link-local addresses, see the **ipv6 enable** or **ipv6 address link-local** command in the *Cisco ASA 5500 Series Command Reference*.

### Detailed Steps

| Command                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv6 address</b> <i>ipv6-prefix/prefix-length</i><br><br><b>Example:</b><br>hostname(config)# ipv6 address<br>2001:0DB8::BA98:0:3210/48 | Assigns a global address. When you assign a global address, link-local addresses are automatically created for each interface.<br><br><b>Note</b> The <b>eui</b> keyword, which is available in routed mode, is not available in transparent mode. The EUI address ties the unicast address to the adaptive security appliance interface MAC address; but because the transparent mode IP address is not tied to an interface, an interface MAC address cannot be used.<br><br>See the <a href="#">“IPv6 Addresses”</a> section on page B-5 for more information about IPv6 addressing. |

## Configuration Examples for the Management IP Address for a Transparent Firewall

The following example sets the IPv4 and IPv6 global management IP addresses, and configures the inside, outside, and management interfaces:

```
hostname(config)# ip address 10.1.1.1 255.255.255.0 standby 10.1.1.2
hostname(config)# ipv6 address 2001:0DB8::BA98:0:3210/48

hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# nameif inside
```

```
hostname(config-if)# security-level 100
hostname(config-if)# no shutdown

hostname(config-if)# interface gigabitethernet 0/1
hostname(config-if)# nameif outside
hostname(config-if)# security-level 0
hostname(config-if)# no shutdown

hostname(config-if)# interface management 0/0
hostname(config-if)# nameif management
hostname(config-if)# security-level 50
hostname(config-if)# ip address 10.1.2.1 255.255.255.0
hostname(config-if)# ipv6 address 2001:0DB8::BA98:0:3211/48
hostname(config-if)# no shutdown
```

## Feature History for the Management IP Address for a Transparent Firewall

Table 7-2 lists the release history for this feature.

**Table 7-2** Feature History for Transparent Mode Management Address

| Feature Name | Releases | Feature Information                                        |
|--------------|----------|------------------------------------------------------------|
| IPv6 support | 8.2(1)   | IPv6 support was introduced for transparent firewall mode. |

# CHAPTER 8

## Configuring DHCP

This chapter describes how to configure the DHCP server, and includes the following topics:

- [Information About DHCP, page 8-1](#)
- [Licensing Requirements for DHCP, page 8-1](#)
- [Guidelines and Limitations, page 8-2](#)
- [Configuring a DHCP Server, page 8-2](#)
- [Configuring DHCP Relay Services, page 8-7](#)
- [DHCP Monitoring Commands, page 8-8](#)
- [Feature History for DHCP, page 8-8](#)

## Information About DHCP

DHCP provides network configuration parameters, such as IP addresses, to DHCP clients. The adaptive security appliance can provide a DHCP server or DHCP relay services to DHCP clients attached to adaptive security appliance interfaces. The DHCP server provides network configuration parameters directly to DHCP clients. DHCP relay passes DHCP requests received on one interface to an external DHCP server located behind a different interface.

## Licensing Requirements for DHCP

[Table 8-1](#) shows the licensing requirements for DHCP.

**Table 8-1**      *Licensing Requirements*

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

For the Cisco ASA 5505 adaptive security appliance, the maximum number of DHCP client addresses varies depending on the license:

- If the limit is 10 hosts, the maximum available DHCP pool is 32 addresses.
- If the limit is 50 hosts, the maximum available DHCP pool is 128 addresses.

- If the number of hosts is unlimited, the maximum available DHCP pool is 256 addresses.

**Note**

By default, the Cisco ASA 5505 adaptive security appliance ships with a 10-user license.

## Guidelines and Limitations

Use the following guidelines to configure the DHCP server:

- You can configure a DHCP server on each interface of the adaptive security appliance. Each interface can have its own pool of addresses to draw from. However the other DHCP settings, such as DNS servers, domain name, options, ping timeout, and WINS servers, are configured globally and used by the DHCP server on all interfaces.
- You cannot configure a DHCP client or DHCP relay services on an interface on which the server is enabled. Additionally, DHCP clients must be directly connected to the interface on which the server is enabled.
- The adaptive security appliance does not support QIP DHCP servers for use with DHCP proxy.
- When it receives a DHCP request, the adaptive security appliance sends a discovery message to the DHCP server. This message includes the IP address (within a subnetwork) configured with the **dhcp-network-scope** command in the group policy. If the server has an address pool that falls within that subnetwork, the server sends the offer message with the pool information to the IP address—not to the source IP address of the discovery message.
- For example, if the server has a pool in the range of 209.165.200.225 to 209.165.200.254, mask 255.255.255.0, and the IP address specified by the **dhcp-network-scope** command is 209.165.200.1, the server sends that pool in the offer message to the adaptive security appliance.

### Failover Guidelines

Supports Active/Active and Active/Standby failover.

### Firewall Mode Guidelines

Supported in routed and transparent firewall modes.

### Context Mode Guidelines

Supported in single mode and multiple context mode.

## Configuring a DHCP Server

This section describes how to configure a DHCP server provided by the adaptive security appliance, and includes the following topics:

- [Enabling the DHCP Server, page 8-3](#)
- [Configuring DHCP Options, page 8-4](#)
- [Using Cisco IP Phones with a DHCP Server, page 8-6](#)
- [DHCP Monitoring Commands, page 8-8](#)

## Enabling the DHCP Server

The adaptive security appliance can act as a DHCP server. DHCP is a protocol that provides network settings to hosts, including the host IP address, the default gateway, and a DNS server.

### Note

The adaptive security appliance DHCP server does not support BOOTP requests. In multiple context mode, you cannot enable the DHCP server or DHCP relay on an interface that is used by more than one context.

To enable the DHCP server on a adaptive security appliance interface, perform the following steps:

|               | Command                                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                        |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>dhcpcd address</b> <i>ip_address-ip_address</i><br><i>interface_name</i><br><br><b>Example:</b><br>hostname(config)# dhcpcd address<br>10.0.1.101-10.0.1.110 inside | Create a DHCP address pool. The adaptive security appliance assigns a client one of the addresses from this pool to use for a given length of time. These addresses are the local, untranslated addresses for the directly connected network.<br><br>The address pool must be on the same subnet as the adaptive security appliance interface. |
| <b>Step 2</b> | <b>dhcpcd dns</b> <i>dns1</i> [ <i>dns2</i> ]<br><br><b>Example:</b><br>hostname(config)# dhcpcd dns 209.165.201.2<br>209.165.202.129                                  | (Optional) Specifies the IP address(es) of the DNS server(s).                                                                                                                                                                                                                                                                                  |
| <b>Step 3</b> | <b>dhcpcd wins</b> <i>wins1</i> [ <i>wins2</i> ]<br><br><b>Example:</b><br>hostname(config)# dhcpcd wins 209.165.201.5                                                 | (Optional) Specifies the IP address(es) of the WINS server(s). You can specify up to two WINS servers.                                                                                                                                                                                                                                         |
| <b>Step 4</b> | <b>dhcpcd lease</b> <i>lease_length</i><br><br><b>Example:</b><br>hostname(config)# dhcpcd lease 3000                                                                  | (Optional) Change the lease length to be granted to the client. This lease equals the amount of time (in seconds) the client can use its allocated IP address before the lease expires. Enter a value between 0 to 1,048,575. The default value is 3600 seconds.                                                                               |
| <b>Step 5</b> | <b>dhcpcd domain</b> <i>domain_name</i><br><br><b>Example:</b><br>hostname(config)# dhcpcd domain example.com                                                          | (Optional) Configures the domain name.                                                                                                                                                                                                                                                                                                         |
| <b>Step 6</b> | <b>dhcpcd ping_timeout</b> <i>milliseconds</i><br><br><b>Example:</b><br>hostname(config)# dhcpcd ping timeout 20                                                      | (Optional) Configures the DHCP ping timeout value. To avoid address conflicts, the adaptive security appliance sends two ICMP ping packets to an address before assigning that address to a DHCP client. This command specifies the timeout value for those packets.                                                                           |

|               | Command                                                                                                              | Purpose                                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 7</b> | <b>dhcpcd option 3 ip</b> <i>gateway_ip</i><br><br><b>Example:</b><br>hostname(config)# dhcpcd option 3 ip 10.10.1.1 | (Transparent Firewall Mode) Defines a default gateway that is sent to DHCP clients. If you do not use the DHCP option 3 to define the default gateway, DHCP clients use the IP address of the management interface. The management interface does not route traffic. |
| <b>Step 8</b> | <b>dhcpcd enable</b> <i>interface_name</i><br><br><b>Example:</b><br>hostname(config)# dhcpcd enable outside         | Enables the DHCP daemon within the adaptive security appliance to listen for DHCP client requests on the enabled interface.                                                                                                                                          |

## Configuring DHCP Options

You can configure the adaptive security appliance to send information for the DHCP options listed in RFC 2132. The DHCP options include the following three categories:

- [Options that Return an IP Address, page 8-4](#)
- [Options that Return a Text String, page 8-4](#)
- [Options that Return a Hexadecimal Value, page 8-5](#)

The adaptive security appliance supports all three categories. To configure a DHCP option, choose one of the following commands:

### Options that Return an IP Address

| Command                                                                                                                                                       | Purpose                                                        |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <b>dhcpcd option</b> <i>code</i> <b>ip</b> <i>addr_1</i> [ <i>addr_2</i> ]<br><br><b>Example:</b><br>hostname(config)# dhcpcd option 2 ip 10.10.1.1 10.10.1.2 | Configures a DHCP option that returns one or two IP addresses. |

### Options that Return a Text String

| Command                                                                                                                                   | Purpose                                              |
|-------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| <b>dhcpcd option</b> <i>code</i> <b>ascii</b> <i>text</i><br><br><b>Example:</b><br>hostname(config)# dhcpcd option 2 ascii examplestring | Configures a DHCP option that returns a text string. |

## Options that Return a Hexadecimal Value

| Command                                                                                                                | Purpose                                                    |
|------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| <code>dhcpd option code hex value</code>                                                                               | Configures a DHCP option that returns a hexadecimal value. |
| <b>Example:</b><br><pre>hostname(config)# dhcpd option 2 hex 22.0011.01.FF1111.00FF.0000.AAAA.1111.1111 .1111.11</pre> |                                                            |

### Note

The adaptive security appliance does not verify that the option type and value that you provide match the expected type and value for the option code as defined in RFC 2132. For example, you can enter the `dhcpd option 46 ascii hello` command, and the adaptive security appliance accepts the configuration, although option 46 is defined in RFC 2132 to expect a single-digit, hexadecimal value. For more information about the option codes and their associated types and expected values, see RFC 2132.

Table 8-2 shows the DHCP options that are not supported by the `dhcpd option` command.

**Table 8-2**      **Unsupported DHCP Options**

| Option Code | Description               |
|-------------|---------------------------|
| 0           | DHCPOPT_PAD               |
| 1           | HCPOPT_SUBNET_MASK        |
| 12          | DHCPOPT_HOST_NAME         |
| 50          | DHCPOPT_REQUESTED_ADDRESS |
| 51          | DHCPOPT_LEASE_TIME        |
| 52          | DHCPOPT_OPTION_OVERLOAD   |
| 53          | DHCPOPT_MESSAGE_TYPE      |
| 54          | DHCPOPT_SERVER_IDENTIFIER |
| 58          | DHCPOPT_RENEWAL_TIME      |
| 59          | DHCPOPT_REBINDING_TIME    |
| 61          | DHCPOPT_CLIENT_IDENTIFIER |
| 67          | DHCPOPT_BOOT_FILE_NAME    |
| 82          | DHCPOPT_RELAY_INFORMATION |
| 255         | DHCPOPT_END               |

DHCP options 3, 66, and 150 are used to configure Cisco IP Phones. For more information about configuring these options, see the [“Using Cisco IP Phones with a DHCP Server”](#) section on page 8-6.

## Using Cisco IP Phones with a DHCP Server

Enterprises with small branch offices that implement a Cisco IP Telephony Voice over IP solution typically implement Cisco CallManager at a central office to control Cisco IP Phones at small branch offices. This implementation allows centralized call processing, reduces the equipment required, and eliminates the administration of additional Cisco CallManager and other servers at branch offices.

Cisco IP Phones download their configuration from a TFTP server. When a Cisco IP Phone starts, if it does not have both the IP address and TFTP server IP address preconfigured, it sends a request with option 150 or 66 to the DHCP server to obtain this information.

- DHCP option 150 provides the IP addresses of a list of TFTP servers.
- DHCP option 66 gives the IP address or the hostname of a single TFTP server.

### Note

Cisco IP Phones might also include DHCP option 3 in their requests, which sets the default route.

A single request might include both options 150 and 66. In this case, the adaptive security appliance DHCP server provides values for both options in the response if they are already configured on the adaptive security appliance.

You can configure the adaptive security appliance to send information for most options listed in RFC 2132. The following examples show the syntax for any option number, as well as the syntax for options 3, 66, and 150:

| Command                                              | Purpose                                                                                        |
|------------------------------------------------------|------------------------------------------------------------------------------------------------|
| <b>dhcpcd option</b> <i>number value</i>             | Provides information for DHCP requests that include an option number as specified in RFC-2132. |
| <b>Example:</b><br>hostname(config)# dhcpcd option 2 |                                                                                                |

| Command                                                                      | Purpose                                                         |
|------------------------------------------------------------------------------|-----------------------------------------------------------------|
| <b>dhcpcd option 66 ascii</b> <i>server_name</i>                             | Provides the IP address or name of a TFTP server for option 66. |
| <b>Example:</b><br>hostname(config)# dhcpcd option 66 ascii<br>exampleserver |                                                                 |

| Command                                                                | Purpose                                                                                                                                                                                                                                                                                                  |
|------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dhcpcd option 150 ip</b> <i>server_ip1</i><br>[ <i>server_ip2</i> ] | Provides the IP address or names of one or two TFTP servers for option 150. The <i>server_ip1</i> is the IP address or name of the primary TFTP server while <i>server_ip2</i> is the IP address or name of the secondary TFTP server. A maximum of two TFTP servers can be identified using option 150. |
| <b>Example:</b><br>hostname(config)# dhcpcd option 150 ip<br>10.10.1.1 |                                                                                                                                                                                                                                                                                                          |

| Command                                                                     | Purpose                 |
|-----------------------------------------------------------------------------|-------------------------|
| <b>dhcpd option 3 ip</b> <i>router_ip1</i>                                  | Sets the default route. |
| <b>Example:</b><br><pre>hostname(config)# dhcpd option 3 ip 10.10.1.1</pre> |                         |

## Configuring DHCP Relay Services

A DHCP relay agent allows the adaptive security appliance to forward DHCP requests from clients to a router connected to a different interface.

The following restrictions apply to the use of the DHCP relay agent:

- The relay agent cannot be enabled if the DHCP server feature is also enabled.
- DHCP clients must be directly connected to the adaptive security appliance and cannot send requests through another relay agent or a router.
- For multiple context mode, you cannot enable DHCP relay on an interface that is used by more than one context.
- DHCP Relay services are not available in transparent firewall mode. A adaptive security appliance in transparent firewall mode only allows ARP traffic through; all other traffic requires an access list. To allow DHCP requests and replies through the adaptive security appliance in transparent mode, you need to configure two access lists, one that allows DHCP requests from the inside interface to the outside, and one that allows the replies from the server in the other direction.
- When DHCP relay is enabled and more than one DHCP relay server is defined, the adaptive security appliance forwards client requests to each defined DHCP relay server. Replies from the servers are also forwarded to the client until the client DHCP relay binding is removed. The binding is removed when the adaptive security appliance receives any of the following DHCP messages: ACK, NACK, or decline.

### Note

You cannot enable DHCP Relay on an interface running DHCP Proxy. You must Remove VPN DHCP configuration first or you will see an error message. This error happens if both DHCP relay and DHCP proxy are enabled. Ensure that either DHCP relay or DHCP proxy are enabled, but not both.

To enable DHCP relay, perform the following steps:

|               | Command                                                                        | Purpose                                                                            |
|---------------|--------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>dhcprelay server</b> <i>ip_address if_name</i>                              | Set the IP address of a DHCP server on a different interface from the DHCP client. |
|               | <b>Example:</b><br><pre>hostname(config)# dhcprelay server 201.168.200.4</pre> | You can use this command up to four times to identify up to four servers.          |
| <b>Step 2</b> | <b>dhcprelay enable</b> <i>interface</i>                                       | Enables DHCP relay on the interface connected to the clients.                      |
|               | <b>Example:</b><br><pre>hostname(config)# dhcprelay enable inside</pre>        |                                                                                    |

|        | Command                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------|-----------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <b>dhcprelay timeout</b> <i>seconds</i><br><br><b>Example:</b><br>hostname(config)# dhcprelay timeout 25              | (Optional) Set the number of seconds allowed for relay address negotiation.                                                                                                                                                                                                                                                                                                                                                                                   |
| Step 4 | <b>dhcprelay setroute</b> <i>interface_name</i><br><br><b>Example:</b><br>hostname(config)# dhcprelay setroute inside | (Optional) Change the first default router address in the packet sent from the DHCP server to the address of the adaptive security appliance interface.<br><br>This action allows the client to set its default route to point to the adaptive security appliance even if the DHCP server specifies a different router.<br><br>If there is no default router option in the packet, the adaptive security appliance adds one containing the interface address. |

## DHCP Monitoring Commands

To monitor DHCP, enter one of the following commands:

| Command                              | Purpose                                       |
|--------------------------------------|-----------------------------------------------|
| <b>show running-config dhcpd</b>     | Shows the current DHCP configuration.         |
| <b>show running-config dhcprelay</b> | Shows the current DHCP relay services status. |

## Feature History for DHCP

Table 8-3 lists the release history for this feature.

**Table 8-3 Feature History for DHCP**

| Feature Name | Releases | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## CHAPTER 9

# Configuring Dynamic DNS

---

This chapter describes how to configure DDNS update methods, and includes the following topics:

- [Information about DDNS, page 9-1](#)
- [Licensing Requirements for DDNS, page 9-2](#)
- [Guidelines and Limitations, page 9-2](#)
- [Configuring DDNS, page 9-2](#)
- [Configuration Examples for DDNS, page 9-3](#)
- [DDNS Monitoring Commands, page 9-6](#)
- [Feature History for DDNS, page 9-6](#)

## Information about DDNS

DDNS update integrates DNS with DHCP. The two protocols are complementary: DHCP centralizes and automates IP address allocation; DDNS update automatically records the association between assigned addresses and hostnames at predefined intervals. DDNS allows frequently changing address-hostname associations to be updated frequently. Mobile hosts, for example, can then move freely on a network without user or administrator intervention. DDNS provides the necessary dynamic update and synchronization of the name-to-address mapping and address-to-name mapping on the DNS server. To configure the DNS server for other uses, see the [“Configuring the DNS Server” section on page 7-11](#). To configure DHCP, see the [“Configuring a DHCP Server” section on page 8-2](#).

EDNS allows DNS requesters to advertise the size of their UDP packets and facilitates the transfer of packets larger than 512 octets. When a DNS server receives a request over UDP, it identifies the size of the UDP packet from the OPT resource record (RR) and scales its response to contain as many resource records as are allowed in the maximum UDP packet size specified by the requester. The size of the DNS packets can be up to 4096 bytes for BIND or 1280 bytes for the Windows 2003 DNS Server. Several additional **message-length maximum** commands are available:

- The existing global limit: **message-length maximum 512**
- A client or server specific limit: **message-length maximum client 4096**
- The dynamic value specified in the OPT RR field: **message-length maximum client auto**

If the three commands are present at the same time, the adaptive security appliance enforces the minimum of the three specified values.

# Licensing Requirements for DDNS

Table 9-1 shows the licensing requirements for DDNS.

**Table 9-1**      *Licensing Requirements*

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Guidelines and Limitations

### Failover Guidelines

Supports Active/Active and Active/Standby failover.

### Firewall Mode Guidelines

Supported in routed firewall mode.

### Context Mode Guidelines

Supported in single and multiple context modes.

Supported in transparent mode for the DNS Client pane.

### IPv6 Guidelines

Supports IPv6.

## Configuring DDNS

This section describes examples for configuring the adaptive security appliance to support Dynamic DNS. DDNS update integrates DNS with DHCP. The two protocols are complementary—DHCP centralizes and automates IP address allocation, while dynamic DNS update automatically records the association between assigned addresses and hostnames. When you use DHCP and dynamic DNS update, this configures a host automatically for network access whenever it attaches to the IP network. You can locate and reach the host using its permanent, unique DNS hostname. Mobile hosts, for example, can move freely without user or administrator intervention.

DDNS provides address and domain name mapping so that hosts can find each other, even though their DHCP-assigned IP addresses change frequently. The DDNS name and address mapping is held on the DHCP server in two resource records: the A RR includes the name-to IP address mapping, while the PTR RR maps addresses to names. Of the two methods for performing DDNS updates—the IETF standard defined by RFC 2136 and a generic HTTP method—the adaptive security appliance supports the IETF method in this release.

The two most common DDNS update configurations are the following:

- The DHCP client updates the A RR, while the DHCP server updates the PTR RR.
- The DHCP server updates both the A RR and PTR RR.

In general, the DHCP server maintains DNS PTR RRs on behalf of clients. Clients may be configured to perform all desired DNS updates. The server may be configured to honor these updates or not. To update the PTR RR, the DHCP server must know the FQDN of the client. The client provides an FQDN to the server using a DHCP option called Client FQDN.

## Configuration Examples for DDNS

The following examples present five common scenarios:

- [Example 1: Client Updates Both A and PTR RRs for Static IP Addresses, page 9-3](#)
- [Example 2: Client Updates Both A and PTR RRs; DHCP Server Honors Client Update Request; FQDN Provided Through Configuration, page 9-3](#)
- [Example 3: Client Includes FQDN Option Instructing Server Not to Update Either RR; Server Overrides Client and Updates Both RRs., page 9-4](#)
- [Example 4: Client Asks Server To Perform Both Updates; Server Configured to Update PTR RR Only; Honors Client Request and Updates Both A and PTR RR, page 9-5](#)
- [Example 5: Client Updates A RR; Server Updates PTR RR, page 9-5](#)

### Example 1: Client Updates Both A and PTR RRs for Static IP Addresses

The following example shows how to configure the client to request that it update both A and PTR resource records for static IP addresses.

To configure this scenario, perform the following steps:

- 
- Step 1** To define a DDNS update method called `ddns-2` that requests that the client update both the A RR and PTR RR, enter the following commands:
- ```
hostname(config)# ddns update method ddns-2
hostname(DDNS-update-method)# ddns both
```
- Step 2** To associate the method `ddns-2` with the `eth1` interface, enter the following commands:
- ```
hostname(DDNS-update-method)# interface eth1
hostname(config-if)# ddns update ddns-2
hostname(config-if)# ddns update hostname asa.example.com
```
- Step 3** To configure a static IP address for `eth1`, enter the following command:
- ```
hostname(config-if)# ip address 10.0.0.40 255.255.255.0
```
- 

### Example 2: Client Updates Both A and PTR RRs; DHCP Server Honors Client Update Request; FQDN Provided Through Configuration

The following example shows how to configure the DHCP client to request that it update both the A and PTR RRs, and the DHCP server to honor these requests.

To configure this scenario, perform the following steps:

- 
- Step 1** To configure the DHCP client to request that the DHCP server perform no updates, enter the following command:
- ```
hostname(config)# dhcp-client update dns server none
```
- Step 2** To create a DDNS update method named ddns-2 on the DHCP client that requests that the client perform both A and PTR updates, enter the following commands:
- ```
hostname(config)# ddns update method ddns-2
hostname(DDNS-update-method)# ddns both
```
- Step 3** To associate the method named ddns-2 with the adaptive security appliance interface named Ethernet0, and enable DHCP on the interface, enter the following commands:
- ```
hostname(DDNS-update-method)# interface Ethernet0
hostname(if-config)# ddns update ddns-2
hostname(if-config)# ddns update hostname asa.example.com
hostname(if-config)# ip address dhcp
```
- Step 4** To configure the DHCP server, enter the following command:
- ```
hostname(if-config)# dhcpd update dns
```
- 

### Example 3: Client Includes FQDN Option Instructing Server Not to Update Either RR; Server Overrides Client and Updates Both RRs.

The following example shows how to configure the DHCP client to include the FQDN option that instruct the DHCP server not to honor either the A or PTR updates. The example also shows how to configure the server to override the client request. As a result, the client does not perform any updates.

To configure this scenario, perform the following steps:

- 
- Step 1** To configure the update method named ddns-2 to request that it make both A and PTR RR updates, enter the following commands:
- ```
hostname(config)# ddns update method ddns-2
hostname(DDNS-update-method)# ddns both
```
- Step 2** To assign the DDNS update method named ddns-2 on interface Ethernet0 and provide the client hostname (asa), enter the following commands:
- ```
hostname(DDNS-update-method)# interface Ethernet0
hostname(if-config)# ddns update ddns-2
hostname(if-config)# ddns update hostname asa.example.com
```
- Step 3** To enable the DHCP client feature on the interface, enter the following commands:
- ```
hostname(if-config)# dhcp client update dns server none
hostname(if-config)# ip address dhcp
```
- Step 4** To configure the DHCP server to override the client update requests, enter the following command:
- ```
hostname(if-config)# dhcpd update dns both override
```
-

## Example 4: Client Asks Server To Perform Both Updates; Server Configured to Update PTR RR Only; Honors Client Request and Updates Both A and PTR RR

The following example shows how to configure the server to perform only PTR RR updates by default. However, the server honors the client request that it perform both A and PTR updates. The server also forms the FQDN by appending the domain name (example.com) to the hostname that the client (asa) has provided.

To configure this scenario, perform the following steps:

- Step 1** To configure the DHCP client on interface Ethernet0, enter the following commands:

```
hostname(config)# interface Ethernet0
hostname(config-if)# dhcp client update dns both
hostname(config-if)# ddns update hostname asa
```

- Step 2** To configure the DHCP server, enter the following commands:

```
hostname(config-if)# dhcpd update dns
hostname(config-if)# dhcpd domain example.com
```

## Example 5: Client Updates A RR; Server Updates PTR RR

The following example shows how to configure the client to update the A resource record and how to configure the server to update the PTR records. Also, the client uses the domain name from the DHCP server to form the FQDN.

To configure this scenario, perform the following steps:

- Step 1** To define the DDNS update method named ddns-2, enter the following commands:

```
hostname(config)# ddns update method ddns-2
hostname(DDNS-update-method)# ddns
```

- Step 2** To configure the DHCP client for interface Ethernet0 and assign the update method to the interface, enter the following commands:

```
hostname(DDNS-update-method)# interface Ethernet0
hostname(config-if)# dhcp client update dns
hostname(config-if)# ddns update ddns-2
hostname(config-if)# ddns update hostname asa
```

- Step 3** To configure the DHCP server, enter the following commands:

```
hostname(config-if)# dhcpd update dns
hostname(config-if)# dhcpd domain example.com
```

# DDNS Monitoring Commands

To monitor DDNS, enter one of the following commands:

Command	Purpose
show running-config ddns	Shows the current DDNS configuration.
show running-config dns server-group	Shows the current DNS server group status.

# Feature History for DDNS

Table 9-2 lists the release history for this feature.

Table 9-2 Feature History for DDNS

Feature Name	Releases	Feature Information
DDNS	7.0(1)	<p>This feature was introduced.</p> <p>The following commands were introduced: <b>ddns</b>, <b>ddns update</b>, <b>dhcp client update dns</b>, <b>dhcpd update dns</b>, <b>show running-config ddns</b>, and <b>show running-config dns server-group</b>.</p>

## CHAPTER 10

# Configuring Web Cache Services Using WCCP

---

This chapter describes how to configure web caching services using WCCP, and includes the following sections:

- [Information About WCCP, page 10-1](#)
- [Guidelines and Limitations, page 10-1](#)
- [Licensing Requirements for WCCP, page 10-2](#)
- [Enabling WCCP Redirection, page 10-3](#)
- [WCCP Monitoring Commands, page 10-4](#)
- [Feature History for WCCP, page 10-4](#)

## Information About WCCP

The purpose of web caching is to reduce latency and network traffic. Previously-accessed web pages are stored in a cache buffer, so if users need the page again, they can retrieve it from the cache instead of the web server.

WCCP specifies interactions between the adaptive security appliance and external web caches. The feature transparently redirects selected types of traffic to a group of web cache engines to optimize resource usage and lower response times. The adaptive security appliance only supports WCCP Version 2.

Using an adaptive security appliance as an intermediary eliminates the need for a separate router to do the WCCP redirection, because the adaptive security appliance redirects requests to cache engines. When the adaptive security appliance determines that a packet needs redirection, it skips TCP state tracking, TCP sequence number randomization, and NAT on these traffic flows.

## Guidelines and Limitations

The following WCCPv2 features are supported for the adaptive security appliance:

- Redirection of multiple TCP and UDP port-directed traffic.
- Authentication for cache engines in a service group.
- Multiple Cache Engines in a service group.
- GRE encapsulation.

The following WCCPv2 features are not supported for the adaptive security appliance:

- Multiple routers in a service group.
- Multicast WCCP.
- The Layer 2 redirect method.
- WCCP source address spoofing.
- WAAS devices.

#### **WCCP Interaction With Other Features**

In the adaptive security appliance implementation of WCCP, the protocol interacts with other configurable features according to the following:

- Cut-through proxy will not work in combination with WCCP.
- An ingress access list entry always takes higher priority over WCCP. For example, if an access list does not permit a client to communicate with a server, then traffic is not redirected to a cache engine. Both ingress interface access lists and egress interface access lists are applied.
- TCP intercept, authorization, URL filtering, inspect engines, and IPS features are not applied to a redirected flow of traffic.
- When a cache engine cannot service a request and a packet is returned, or when a cache miss happens on a cache engine and it requests data from a web server, then the contents of the traffic flow is subject to all the other configured features of the adaptive security appliance.
- If you have two WCCP services and they use two different redirection ACLs that overlap and match the same packets (with a deny or a permit action), the packets behave according to the first service-group found and installed rules. The packets are not passed thorough all service-groups.

#### **Failover Guidelines**

Supports Active/Active and Active/Standby failover. WCCP redirect tables are not replicated to standby units. After a failover, packets are not redirected until the tables are rebuilt. Sessions redirected before failover are probably reset by the web server.

#### **Firewall Mode Guidelines**

Supported in routed and transparent firewall modes.

#### **Context Mode Guidelines**

Supported in single mode and multiple context mode.

#### **IPv6 Guidelines**

Supports IPv6.

## **Licensing Requirements for WCCP**

Table 10-1 shows the licensing requirements for WCCP.

**Table 10-1     Licensing Requirements**

Model	License Requirement
All models	Base License.

## Enabling WCCP Redirection

WCCP redirection is supported only on the ingress of an interface. The only topology that the adaptive security appliance supports is when client and cache engine are behind the same interface of the adaptive security appliance and the cache engine can directly communicate with the client, without going through the adaptive security appliance.

The following configuration tasks assume you have already installed and configured the cache engines that you want to include in your network.

To configure WCCP redirection, perform the following steps:

	Command	Purpose
Step 1	<p><b>wccp {web-cache   service_number} [redirect-list access_list] [group-list access_list] [password password]</b></p> <p><b>Example:</b> hostname (config)# wccp web-cache</p>	<p>Enables a WCCP service group and identifies the service to be redirected. (Optional) Also defines which cache engines can participate in the service group, and what traffic should be redirected to the cache engine.</p> <p>The standard service is web-cache, which intercepts TCP port 80 (HTTP) traffic and redirects that traffic to the cache engines, but you can identify a service number (if desired) between 0 and 254. For example, to transparently redirect native FTP traffic to a cache engine, use WCCP service 60. You can enter this command multiple times for each service group that you want to enable.</p> <p>The <b>redirect-list access_list</b> argument controls traffic that is redirected to this service group.</p> <p>The <b>group-list access_list</b> argument determines which web cache IP addresses are allowed to participate in the service group.</p> <p>The <b>password password</b> argument specifies MD5 authentication for messages that are received from the service group. Messages that are not accepted by the authentication are discarded.</p>
Step 2	<p><b>wccp interface interface_name {web-cache   service_number} redirect in</b></p> <p><b>Example:</b> hostname (config)# wccp interface inside web-cache redirect in</p>	<p>Identifies an interface and enables WCCP redirection on the interface.</p> <p>The standard service is web-cache, which intercepts TCP port 80 (HTTP) traffic and redirects that traffic to the cache engines, but you can identify a service number (if desired) between 0 and 254. For example, to transparently redirect native FTP traffic to a cache engine, use WCCP service 60. You can enter this command multiple times for each service group that you want to enable.</p>

### Examples

For example, to enable the standard web-cache service and redirect HTTP traffic that enters the inside interface to a web cache, enter the following commands:

```
hostname (config)# wccp web-cache
```

```
hostname (config)# wccp interface inside web-cache redirect in
```

## WCCP Monitoring Commands

To monitor WCCP, enter one of the following commands:

Command	Purpose
<code>show running-config wccp</code>	Shows the current WCCP configuration.
<code>show running-config wccp interface</code>	Shows the current WCCP interfaces status.

## Feature History for WCCP

[Table 10-2](#) lists the release history for this feature.

**Table 10-2**      *Feature History for WCCP*

Feature Name	Releases	Feature Information
WCCP	7.2(1)	This feature was introduced. The following commands were introduced: <b>wccp</b> and <b>wccp interface</b> .

# CHAPTER 11

## Configuring Objects

---

Objects are reusable components for use in your configuration. They can be defined and used in adaptive security appliance configurations in the place of inline IP addresses. Objects make it easy to maintain your configurations because you can modify an object in one place and have it be reflected in all other places that are referencing it. Without objects you would have to modify the parameters for every feature when required, instead of just once. For example, if a network object defines an IP address and subnet mask, and you want to change the address, you only need to change it in the object definition, not in every feature that refers to that IP address.

This chapter describes how to configure objects, and it includes the following sections:

- [Configuring Objects and Groups, page 11-1](#)
- [Configuring Regular Expressions, page 11-12](#)
- [Scheduling Extended Access List Activation, page 11-16](#)

## Configuring Objects and Groups

This section includes the following topics:

- [Information About Objects and Groups, page 11-1](#)
- [Licensing Requirements for Objects and Groups, page 11-2](#)
- [Guidelines and Limitations for Objects and Groups, page 11-3](#)
- [Configuring Objects, page 11-3](#)
- [Configuring Object Groups, page 11-6](#)
- [Monitoring Objects and Groups, page 11-11](#)
- [Feature History for Objects and Groups, page 11-12](#)

## Information About Objects and Groups

The adaptive security appliance supports objects and object groups. You can attach or detach objects from one or more object groups when needed, ensuring that the objects are not duplicated but can be re-used wherever needed.

This section includes the following topics:

- [Information About Objects, page 11-2](#)

- [Information About Object Groups, page 11-2](#)

## Information About Objects

Objects are created in and used by the adaptive security appliance in the place of an inline IP address in any given configuration. You can define an object with a particular IP address and netmask pair or a protocol (and, optionally, a port) and use this object in several configurations. The advantage is that whenever you want to modify the configurations created to this IP address or protocol, you do not need to modify all rules in the running configuration. You can modify the object, and then the change automatically applies to all rules that use the specified object. You can configure two types of objects: network objects and service objects. These objects can be used in Network Address Translation (NAT), access lists, and object groups.

## Information About Object Groups

By grouping like objects together, you can use the object group in an ACE instead of having to enter an ACE for each object separately. You can create the following types of object groups:

- Protocol
- Network
- Service
- ICMP type

For example, consider the following three object groups:

- MyServices—Includes the TCP and UDP port numbers of the service requests that are allowed access to the internal network.
- TrustedHosts—Includes the host and network addresses allowed access to the greatest range of services and servers.
- PublicServers—Includes the host addresses of servers to which the greatest access is provided.

After creating these groups, you could use a single ACE to allow trusted hosts to make specific service requests to a group of public servers.

You can also nest object groups in other object groups.

## Licensing Requirements for Objects and Groups

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

## Guidelines and Limitations for Objects and Groups

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported in routed and transparent firewall modes.

### IPv6 Guidelines

Supports IPv6, with limitations. (See the [Additional Guidelines and Limitations, page 11-3](#).)

### Additional Guidelines and Limitations

The following guidelines and limitations apply to object groups:

- Objects and object groups share the same name space.
- Object groups must have unique names. While you might want to create a network object group named “Engineering” and a service object group named “Engineering,” you need to add an identifier (or “tag”) to the end of at least one object group name to make it unique. For example, you can use the names “Engineering\_admins” and “Engineering\_hosts” to make the object group names unique and to aid in identification.
- You cannot remove an object group or make an object group empty if it is used in a command.
- The adaptive security appliance does not support IPv6 nested object groups, so you cannot group an object with IPv6 entities under another IPv6 object group.

## Configuring Objects

This section includes the following topics:

- [Configuring a Network Object, page 11-3](#)
- [Configuring a Service Object, page 11-4](#)

### Configuring a Network Object

A network object contains a single IP address/mask pair. Network objects can be of three types: host, subnet, or range.

You can also configure auto NAT as part of the object definition; see [Chapter 28, “Configuring Network Object NAT,”](#) for more information.

## Detailed Steps

	Command	Purpose
Step 1	<b>object network</b> <i>obj_name</i>  <b>Example:</b> hostname(config)# object-network OBJECT1	Creates a new network object. The <i>obj_name</i> is a text string up to 64 characters in length and can be any combination of letters, digits, and the following characters: <ul style="list-style-type: none"> <li>underscore “_”</li> <li>dash “-”</li> <li>period “.”</li> </ul> The prompt changes to network object configuration mode.
Step 2	{ <b>host</b> <i>ip_addr</i>   <b>subnet</b> <i>net_addr net_mask</i>   <b>range</b> <i>ip_addr_1 ip_addr_2</i> }  <b>Example:</b> hostname(config-network-object)# host 10.2.2.2	Assigns the IP address to the named object. You can configure a host address, a subnet, or a range of addresses.
Step 3	<b>description</b> <i>text</i>  <b>Example:</b> hostname(config-network-object)# description Engineering Network	Adds a description to the object.

## Examples

To create a network object, enter the following commands:

```
hostname (config)# object network OBJECT1
hostname (config-network-object)# host 10.2.2.2
```

## Configuring a Service Object

A service object contains a protocol and optional source and/or destination port.

## Detailed Steps

	Command	Purpose
Step 1	<b>object service</b> <i>obj_name</i>  <b>Example:</b> <pre>hostname(config)# object-service SERVOBJECT1</pre>	<p>Creates a new service object. The <i>obj_name</i> is a text string up to 64 characters in length and can be any combination of letters, digits, and the following characters:</p> <ul style="list-style-type: none"> <li>• underscore “_”</li> <li>• dash “-”</li> <li>• period “.”</li> </ul> <p>The prompt changes to service object configuration mode.</p>
Step 2	<pre><b>service</b> {<i>protocol</i>   <b>icmp</b> <i>icmp-type</i>   <b>icmp6</b> <i>icmp6-type</i>   {<b>tcp</b>   <b>udp</b>} [<b>source</b> <i>operator</i> <i>port</i>] [<b>destination</b> <i>operator</i> <i>port</i>]}</pre> <b>Example:</b> <pre>hostname(config-service-object)# service tcp source eq www destination eq ssh</pre>	<p>Creates a service object for the source mapped address.</p> <p>The <i>protocol</i> argument specifies an IP protocol name or number.</p> <p>The <b>icmp</b>, <b>tcp</b>, or <b>udp</b> keywords specify that this service object is for either the ICMP, TCP, or UDP protocol.</p> <p>The <i>icmp-type</i> argument names the ICMP type.</p> <p>The <b>icmp6</b> keyword specifies that the service type is for ICMP version 6 connections.</p> <p>The <i>icmp6-type</i> argument names the ICMP version 6 type.</p> <p>The <b>source</b> keyword specifies the source port.</p> <p>The <b>destination</b> keyword specifies the destination port.</p> <p>The <i>operator port</i> argument specifies a single port/code value that supports configuring the port for the protocol. You can specify “eq,” “neq,” “lt,” “gt,” and “range” when configuring a port for TCP or UDP. The “range” operator lists the beginning port and ending port.</p>

## Example

To create a service object, enter the following commands:

```
hostname (config)# object service SERVOBJECT1
hostname (config-service-object)# service tcp source eq www destination eq ssh
```

## Configuring Object Groups

This section includes the following topics:

- [Adding a Protocol Object Group, page 11-6](#)
- [Adding a Network Object Group, page 11-7](#)
- [Adding a Service Object Group, page 11-8](#)
- [Adding an ICMP Type Object Group, page 11-9](#)
- [Nesting Object Groups, page 11-10](#)
- [Removing Object Groups, page 11-11](#)

### Adding a Protocol Object Group

To add or change a protocol object group, perform the steps in this section. After you add the group, you can add more objects as required by following this procedure again for the same group name and specifying additional objects. You do not need to reenter existing objects; the commands you already set remain in place unless you remove them with the **no** form of the command.

#### Detailed Steps

	Command	Purpose
Step 1	<b>object-group protocol</b> <i>obj_grp_id</i>  <b>Example:</b> <pre>hostname(config)# object-group protocol tcp_udp_icmp</pre>	Adds a protocol group. The <i>obj_grp_id</i> is a text string up to 64 characters in length and can be any combination of letters, digits, and the following characters: <ul style="list-style-type: none"> <li>• underscore “_”</li> <li>• dash “-”</li> <li>• period “.”</li> </ul> The prompt changes to protocol configuration mode.
Step 2	<b>description</b> <i>text</i>  <b>Example:</b> <pre>hostname(config-protocol)# description New Group</pre>	(Optional) Adds a description. The description can be up to 200 characters.
Step 3	<b>protocol-object</b> <i>protocol</i>  <b>Example:</b> <pre>hostname(config-protocol)# protocol-object tcp</pre>	Defines the protocols in the group. Enter the command for each protocol. The protocol is the numeric identifier of the specified IP protocol (1 to 254) or a keyword identifier (for example, <b>icmp</b> , <b>tcp</b> , or <b>udp</b> ). To include all IP protocols, use the keyword <b>ip</b> . For a list of protocols that you can specify, see the <a href="#">“Protocols and Applications”</a> section on page B-11.

#### Example

To create a protocol group for TCP, UDP, and ICMP, enter the following commands:

```
hostname (config)# object-group protocol tcp_udp_icmp
hostname (config-protocol)# protocol-object tcp
hostname (config-protocol)# protocol-object udp
```

```
hostname (config-protocol)# protocol-object icmp
```

## Adding a Network Object Group

A network object group supports IPv4 and IPv6 addresses.

To add or change a network object group, perform the steps in this section. After you add the group, you can add more objects as required by following this procedure again for the same group name and specifying additional objects. You do not need to reenter existing objects; the commands you already set remain in place unless you remove them with the no form of the command.

### Detailed Steps

	Command	Purpose
Step 1	<b>object-group network</b> <i>grp_id</i>  <b>Example:</b> hostname(config)# <b>object-group network</b> admins	Adds a network group.  The <i>grp_id</i> is a text string up to 64 characters in length and can be any combination of letters, digits, and the following characters: <ul style="list-style-type: none"> <li>• underscore “_”</li> <li>• dash “-”</li> <li>• period “.”</li> </ul> The prompt changes to protocol configuration mode.
Step 2	<b>description</b> <i>text</i>  <b>Example:</b> hostname(config-network)# <b>description</b> Administrator Addresses	(Optional) Adds a description. The description can be up to 200 characters.
Step 3	<b>network-object</b> { <b>object</b> <i>name</i>   <i>host ip_address</i>   <i>ip_address mask</i> }  <b>Example:</b> hostname(config-network)# <b>network-object</b> host 10.2.2.4	The <b>object</b> keyword adds an additional object to the network object group.  Defines the networks in the group. Enter the command for each network or address.

### Example

To create a network group that includes the IP addresses of three administrators, enter the following commands:

```
hostname (config)# object-group network admins
hostname (config-protocol)# description Administrator Addresses
hostname (config-protocol)# network-object host 10.2.2.4
hostname (config-protocol)# network-object host 10.2.2.78
hostname (config-protocol)# network-object host 10.2.2.34
```

## Adding a Service Object Group

To add or change a service object group, perform the steps in this section. After you add the group, you can add more objects as required by following this procedure again for the same group name and specifying additional objects. You do not need to reenter existing objects; the commands you already set remain in place unless you remove them with the **no** form of the command.

### Detailed Steps

	Command	Purpose
Step 1	<b>object-group service <i>grp_id</i> {tcp   udp   tcp-udp}</b>  <b>Example:</b> <pre>hostname(config)# object-group service services1 tcp-udp</pre>	<p>Adds a service group.</p> <p>The <b>object</b> keyword adds an additional object to the service object group.</p> <p>The <i>grp_id</i> is a text string up to 64 characters in length and can be any combination of letters, digits, and the following characters:</p> <ul style="list-style-type: none"> <li>underscore “_”</li> <li>dash “-”</li> <li>period “.”</li> </ul> <p>Specify the protocol for the services (ports) you want to add with either the <b>tcp</b>, <b>udp</b>, or <b>tcp-udp</b> keywords. Enter the <b>tcp-udp</b> keyword if your service uses both TCP and UDP with the same port number, for example, DNS (port53).</p> <p>The prompt changes to service configuration mode.</p>
Step 2	<b>description <i>text</i></b>  <b>Example:</b> <pre>hostname(config-service)# description DNS Group</pre>	<p>(Optional) Adds a description. The description can be up to 200 characters.</p>
Step 3	<b>port-object {eq <i>port</i>   range <i>begin_port</i> <i>end_port</i>}</b>  <b>Example:</b> <pre>hostname(config-service)# port-object eq domain</pre>	<p>Defines the ports in the group. Enter the command for each port or range of ports. For a list of permitted keywords and well-known port assignments, see the <a href="#">“Protocols and Applications”</a> section on page B-11.</p>

### Example

To create service groups that include DNS (TCP/UDP), LDAP (TCP), and RADIUS (UDP), enter the following commands:

```
hostname (config)# object-group service services1 tcp-udp
hostname (config-service)# description DNS Group
hostname (config-service)# port-object eq domain

hostname (config)# object-group service services2 udp
hostname (config-service)# description RADIUS Group
hostname (config-service)# port-object eq radius
```

```
hostname (config-service)# port-object eq radius-acct

hostname (config)# object-group service services3 tcp
hostname (config-service)# description LDAP Group
hostname (config-service)# port-object eq ldap
```

## Adding an ICMP Type Object Group

To add or change an ICMP type object group, perform the steps in this section. After you add the group, you can add more objects as required by following this procedure again for the same group name and specifying additional objects. You do not need to reenter existing objects; the commands you already set remain in place unless you remove them with the **no** form of the command.

### Detailed Steps

	Command	Purpose
Step 1	<b>object-group icmp-type</b> <i>grp_id</i>  <b>Example:</b> hostname(config)# object-group icmp-type ping	Adds an ICMP type object group. The <i>grp_id</i> is a text string up to 64 characters in length and can be any combination of letters, digits, and the following characters: <ul style="list-style-type: none"> <li>underscore “_”</li> <li>dash “-”</li> <li>period “.”</li> </ul> The prompt changes to ICMP type configuration mode.
Step 2	<b>description</b> <i>text</i>  <b>Example:</b> hostname(config-icmp-type)# description Ping Group	(Optional) Adds a description. The description can be up to 200 characters.
Step 3	<b>icmp-object</b> <i>icmp-type</i>  <b>Example:</b> hostname(config-icmp-type)# icmp-object echo-reply	Defines the ICMP types in the group. Enter the command for each type. For a list of ICMP types, see the <a href="#">“ICMP Types” section on page B-15</a> .

### Example

Create an ICMP type group that includes echo-reply and echo (for controlling ping) by entering the following commands:

```
hostname (config)# object-group icmp-type ping
hostname (config-service)# description Ping Group
hostname (config-service)# icmp-object echo
hostname (config-service)# icmp-object echo-reply
```

## Nesting Object Groups

You can nest object groups hierarchically so that one object group can contain other object groups of the same type and you can mix and match nested group objects and regular objects within an object group. The security appliance does not support IPv6 nested object groups, however, so you cannot group an object with IPv6 entities under another IPv6 object-group.

To nest an object group within another object group of the same type, first create the group that you want to nest (see the [“Configuring Object Groups”](#) section on page 11-6), and then perform the steps in this section.

### Detailed Steps

	Command	Purpose
Step 1	<b>object-group group</b> {{protocol   network   icmp-type} grp_id  service grp_id {tcp   udp   tcp-udp}}  <b>Example:</b> hostname(config)# object-group network Engineering_group	Adds or edits the specified object group type under which you want to nest another object group.  The <b>service_grp_id</b> is a text string up to 64 characters in length and can be any combination of letters, digits, and the following characters: <ul style="list-style-type: none"> <li>• underscore “_”</li> <li>• dash “-”</li> <li>• period “.”</li> </ul>
Step 2	<b>group-object group_id</b>  <b>Example:</b> hostname(config-network)# group-object Engineering_groups	Adds the specified group under the object group you specified in Step 1. The nested group must be of the same type. You can mix and match nested group objects and regular objects within an object group.

### Examples

Create network object groups for privileged users from various departments by entering the following commands:

```
hostname (config)# object-group network eng
hostname (config-network)# network-object host 10.1.1.5
hostname (config-network)# network-object host 10.1.1.9
hostname (config-network)# network-object host 10.1.1.89

hostname (config)# object-group network hr
hostname (config-network)# network-object host 10.1.2.8
hostname (config-network)# network-object host 10.1.2.12

hostname (config)# object-group network finance
hostname (config-network)# network-object host 10.1.4.89
hostname (config-network)# network-object host 10.1.4.100
```

You then nest all three groups together as follows:

```
hostname (config)# object-group network admin
hostname (config-network)# group-object eng
hostname (config-network)# group-object hr
hostname (config-network)# group-object finance
```

You only need to specify the admin object group in your ACE as follows:

```
hostname (config)# access-list ACL_IN extended permit ip object-group admin host
209.165.201.29
```

## Removing Object Groups

You can remove a specific object group or remove all object groups of a specified type; however, you cannot remove an object group or make an object group empty if it is used in an access list.

### Detailed Step

<b>Step 1</b>	Do one of the following:	
	<pre>no object-group grp_id</pre> <p><b>Example:</b></p> <pre>hostname(config)# no object-group Engineering_host</pre>	<p>Removes the specified object group. The <i>grp_id</i> is a text string up to 64 characters in length and can be any combination of letters, digits, and the following characters:</p> <ul style="list-style-type: none"> <li>• underscore “_”</li> <li>• dash “-”</li> <li>• period “.”</li> </ul>
	<pre>clear object-group [protocol   network   services   icmp-type]</pre> <p><b>Example:</b></p> <pre>hostname(config)# clear-object group network</pre>	<p>Removes all object groups of the specified type.</p> <p> <b>Note</b> If you do not enter a type, all object groups are removed.</p>

## Monitoring Objects and Groups

To monitor objects and groups, enter the following commands:

Command	Purpose
<b>show access-list</b>	Displays the access list entries that are expanded out into individual entries without their object groupings.
<b>show running-config object-group</b>	Displays all current object groups.
<b>show running-config object-group</b> <i>grp_id</i>	Displays the current object groups by their group ID.
<b>show running-config object-group</b> <i>grp_type</i>	Displays the current object groups by their group type.

## Feature History for Objects and Groups

Table 1 lists the release history for this feature.

**Table 1** Feature History for Object Groups

Feature Name	Releases	Feature Information
Object groups	7.0(1)	Object groups simplify access list creation and maintenance.  The following commands were introduced or modified: <b>object-group</b> <i>protocol</i> , <b>object-group</b> <i>network</i> , <b>object-group</b> <i>service</i> , <b>object-group</b> <i>icmp_type</i> .
Objects	8.3(1)	Object support was introduced.  The following commands were introduced or modified <b>object-network</b> , <b>object-service</b> , <b>object-group</b> <i>network</i> , <b>object-group</b> <i>service</i> , <b>network object</b> , <b>access-list</b> <b>extended</b> , <b>access-list</b> <i>webtype</i> , <b>access-list</b> <i>remark</i>

## Configuring Regular Expressions

A regular expression matches text strings either literally as an exact string, or by using *metacharacters* so that you can match multiple variants of a text string. You can use a regular expression to match the content of certain application traffic; for example, you can match a URL string inside an HTTP packet. This section describes how to create a regular expression and includes the following topics:

- [Creating a Regular Expression, page 11-12](#)
- [Creating a Regular Expression Class Map, page 11-15](#)

## Creating a Regular Expression

A regular expression matches text strings either literally as an exact string, or by using *metacharacters* so you can match multiple variants of a text string. You can use a regular expression to match the content of certain application traffic; for example, you can match a URL string inside an HTTP packet.

### Guidelines

Use **Ctrl+V** to escape all of the special characters in the CLI, such as question mark (?) or a tab. For example, type **d[Ctrl+V]?g** to enter **d?g** in the configuration.

See the **regex** command in the *Cisco ASA 5500 Series Command Reference* for performance impact information when matching a regular expression to packets.

#### Note

As an optimization, the adaptive security appliance searches on the deobfuscated URL. Deobfuscation compresses multiple forward slashes (/) into a single slash. For strings that commonly use double slashes, like “http://”, be sure to search for “http:” instead.

Table 11-2 lists the metacharacters that have special meanings.

**Table 11-2** *regex Metacharacters*

Character	Description	Notes
.	Dot	Matches any single character. For example, <b>d.g</b> matches dog, dag, dtg, and any word that contains those characters, such as doggonnit.
(exp)	Subexpression	A subexpression segregates characters from surrounding characters, so that you can use other metacharacters on the subexpression. For example, <b>d(ola)g</b> matches dog and dag, but <b>dolag</b> matches do and ag. A subexpression can also be used with repeat quantifiers to differentiate the characters meant for repetition. For example, <b>ab(xy){3}z</b> matches abxyxyxyz.
	Alternation	Matches either expression it separates. For example, <b>dog cat</b> matches dog or cat.
?	Question mark	A quantifier that indicates that there are 0 or 1 of the previous expression. For example, <b>lo?se</b> matches lse or lose.  <b>Note</b> You must enter <b>Ctrl+V</b> and then the question mark or else the help function is invoked.
*	Asterisk	A quantifier that indicates that there are 0, 1 or any number of the previous expression. For example, <b>lo*se</b> matches lse, lose, loose, and so on.
+	Plus	A quantifier that indicates that there is at least 1 of the previous expression. For example, <b>lo+se</b> matches lose and loose, but not lse.
{x} or {x,}	Minimum repeat quantifier	Repeat at least <i>x</i> times. For example, <b>ab(xy){2,}z</b> matches abxyxyz, abxyxyxyz, and so on.
[abc]	Character class	Matches any character in the brackets. For example, <b>[abc]</b> matches a, b, or c.
[^abc]	Negated character class	Matches a single character that is not contained within the brackets. For example, <b>[^abc]</b> matches any character other than a, b, or c. <b>[^A-Z]</b> matches any single character that is not an uppercase letter.
[a-c]	Character range class	Matches any character in the range. <b>[a-z]</b> matches any lowercase letter. You can mix characters and ranges: <b>[abcq-z]</b> matches a, b, c, q, r, s, t, u, v, w, x, y, z, and so does <b>[a-cq-z]</b> .  The dash (-) character is literal only if it is the last or the first character within the brackets: <b>[abc-]</b> or <b>[-abc]</b> .
“”	Quotation marks	Preserves trailing or leading spaces in the string. For example, <b>“test”</b> preserves the leading space when it looks for a match.
^	Caret	Specifies the beginning of a line.

**Table 11-2** *regex Metacharacters (continued)*

Character	Description	Notes
\	Escape character	When used with a metacharacter, matches a literal character. For example, \[ matches the left square bracket.
<i>char</i>	Character	When character is not a metacharacter, matches the literal character.
\r	Carriage return	Matches a carriage return 0x0d.
\n	Newline	Matches a new line 0x0a.
\t	Tab	Matches a tab 0x09.
\f	Formfeed	Matches a form feed 0x0c.
\xNN	Escaped hexadecimal number	Matches an ASCII character using hexadecimal (exactly two digits).
\NNN	Escaped octal number	Matches an ASCII character as octal (exactly three digits). For example, the character 040 represents a space.

## Detailed Steps

- Step 1** To test a regular expression to make sure it matches what you think it will match, enter the following command:

```
hostname(config)# test regex input_text regular_expression
```

Where the *input\_text* argument is a string you want to match using the regular expression, up to 201 characters in length.

The *regular\_expression* argument can be up to 100 characters in length.

Use **Ctrl+V** to escape all of the special characters in the CLI. For example, to enter a tab in the input text in the **test regex** command, you must enter **test regex “test[Ctrl+V Tab]” “test\t”**.

If the regular expression matches the input text, you see the following message:

```
INFO: Regular expression match succeeded.
```

If the regular expression does not match the input text, you see the following message:

```
INFO: Regular expression match failed.
```

- Step 2** To add a regular expression after you tested it, enter the following command:

```
hostname(config)# regex name regular_expression
```

Where the *name* argument can be up to 40 characters in length.

The *regular\_expression* argument can be up to 100 characters in length.

## Examples

The following example creates two regular expressions for use in an inspection policy map:

```
hostname(config)# regex url_example example\.com
```

```
hostname(config)# regex url_example2 example2\.com
```

## Creating a Regular Expression Class Map

A regular expression class map identifies one or more regular expressions. You can use a regular expression class map to match the content of certain traffic; for example, you can match URL strings inside HTTP packets.

### Detailed Steps

---

**Step 1** Create one or more regular expressions according to the [“Configuring Regular Expressions”](#) section.

**Step 2** Create a class map by entering the following command:

```
hostname(config)# class-map type regex match-any class_map_name  
hostname(config-cmap)#
```

Where *class\_map\_name* is a string up to 40 characters in length. The name “class-default” is reserved. All types of class maps use the same name space, so you cannot reuse a name already used by another type of class map.

The **match-any** keyword specifies that the traffic matches the class map if it matches at least one of the regular expressions.

The CLI enters class-map configuration mode.

**Step 3** (Optional) Add a description to the class map by entering the following command:

```
hostname(config-cmap)# description string
```

**Step 4** Identify the regular expressions you want to include by entering the following command for each regular expression:

```
hostname(config-cmap)# match regex regex_name
```

---

### Examples

The following example creates two regular expressions, and adds them to a regular expression class map. Traffic matches the class map if it includes the string “example.com” or “example2.com.”

```
hostname(config)# regex url_example example\.com  
hostname(config)# regex url_example2 example2\.com  
hostname(config)# class-map type regex match-any URLs  
hostname(config-cmap)# match regex url_example  
hostname(config-cmap)# match regex url_example2
```

# Scheduling Extended Access List Activation

This section includes the following topics:

- [Information About Scheduling Access List Activation, page 11-16](#)
- [Licensing Requirements for Scheduling Access List Activation, page 11-16](#)
- [Guidelines and Limitations for Scheduling Access List Activation, page 11-16](#)
- [Configuring and Applying Time Ranges, page 11-17](#)
- [Configuration Examples for Scheduling Access List Activation, page 11-18](#)
- [Feature History for Scheduling Access List Activation, page 11-18](#)

## Information About Scheduling Access List Activation

You can schedule each ACE in an access list to be activated at specific times of the day and week by applying a time range to the ACE.

## Licensing Requirements for Scheduling Access List Activation

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

## Guidelines and Limitations for Scheduling Access List Activation

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported in routed and transparent firewall modes.

### IPv6 Guidelines

Supports IPv6.

### Additional Guidelines and Limitations

The following guidelines and limitations apply to using object groups with access lists:

- Users could experience a delay of approximately 80 to 100 seconds after the specified end time for the ACL to become inactive. For example, if the specified end time is 3:50, because the end time is inclusive, the command is picked up anywhere between 3:51:00 and 3:51:59. After the command is picked up, the adaptive security appliance finishes any currently running task and then services the command to deactivate the ACL.
- Multiple periodic entries are allowed per **time-range** command. If a **time-range** command has both **absolute** and **periodic** values specified, then the **periodic** commands are evaluated only after the **absolute** start time is reached, and they are not further evaluated after the **absolute** end time is reached.

## Configuring and Applying Time Ranges

You can add a time range to implement a time-based access list. To identify the time range, perform the steps in this section.

### Detailed Steps

	Command	Purpose
Step 1	<b>time-range</b> <i>name</i>  <b>Example:</b> hostname(config)# time range Sales	Identifies the time-range name.
Step 2	Do one of the following:  <b>periodic</b> <i>days-of-the-week time to</i> <i>[days-of-the-week] time</i>  <b>Example:</b> hostname(config-time-range)# periodic monday 7:59 to friday 17:01	Specifies a recurring time range.  You can specify the following values for <i>days-of-the-week</i> : <ul style="list-style-type: none"> <li>• <b>monday, tuesday, wednesday, thursday, friday, saturday, or sunday.</b></li> <li>• <b>daily</b></li> <li>• <b>weekdays</b></li> <li>• <b>weekend</b></li> </ul> The <i>time</i> is in the format <i>hh:mm</i> . For example, 8:00 is 8:00 a.m. and 20:00 is 8:00 p.m.

Command	Purpose
absolute <b>start</b> <i>time date</i> [ <b>end</b> <i>time date</i> ]  <b>Example:</b> hostname(config-time-range)# absolute start 7:59 2 january 2009	Specifies an absolute time range.  The <i>time</i> is in the format <i>hh:mm</i> . For example, 8:00 is 8:00 a.m. and 20:00 is 8:00 p.m.  The <i>date</i> is in the format <i>day month year</i> ; for example, <b>1 january 2006</b> .
<b>Step 3</b> access-list <i>access_list_name</i> [ <b>extended</b> ] { <b>deny</b> / <b>permit</b> }...[ <b>time-range</b> <i>name</i> ]  <b>Example:</b> hostname(config)# access list Marketing extended deny tcp host 209.165.200.225 host 209.165.201.1 time-range Pacific_Coast	Applies the time range to an ACE.   <b>Note</b> If you also enable logging for the ACE, use the <b>log</b> keyword before the <b>time-range</b> keyword. If you disable the ACE using the <b>inactive</b> keyword, use the <b>inactive</b> keyword as the last keyword.  See <a href="#">Chapter 13, “Adding an Extended Access List,”</a> for complete <b>access-list</b> command syntax.

### Example

The following example binds an access list named “Sales” to a time range named “New\_York\_Minute”:

```
hostname(config)# access-list Sales line 1 extended deny tcp host 209.165.200.225 host
209.165.201.1 time-range New_York_Minute
```

## Configuration Examples for Scheduling Access List Activation

The following is an example of an absolute time range beginning at 8:00 a.m. on January 1, 2006. Because no end time and date are specified, the time range is in effect indefinitely.

```
hostname(config)# time-range for2006
hostname(config-time-range)# absolute start 8:00 1 january 2006
```

The following is an example of a weekly periodic time range from 8:00 a.m. to 6:00 p.m on weekdays:

```
hostname(config)# time-range workinghours
hostname(config-time-range)# periodic weekdays 8:00 to 18:00
```

## Feature History for Scheduling Access List Activation

[Table 3](#) lists the release history for this feature.

**Table 3** Feature History for Scheduling Access List Activation

Feature Name	Releases	Feature Information
Scheduling access list activation	7.0	You can schedule each ACE in an access list to be activated at specific times of the day and week.  The following commands were introduced or modified: <b>object-group protocol</b> , <b>object-group network</b> , <b>object-group service</b> , <b>object-group icmp_type</b> .

## **PART 3**

### **Configuring Access Lists**

# CHAPTER 12

## Information About Access Lists

---

Cisco ASA 5500 series adaptive security appliances provide basic traffic filtering capabilities with access lists, which control access in your network by preventing certain traffic from entering or exiting. This chapter describes access lists and shows how to add them to your network configuration.

Access lists are made up of one or more access control entries (ACEs). An ACE is a single entry in an access list that specifies a permit or deny rule (to forward or drop the packet) and is applied to a protocol, to a source and destination IP address or network, and, optionally, to the source and destination ports.

Access lists can be configured for all routed and network protocols (IP, AppleTalk, and so on) to filter the packets of those protocols as the packets pass through a router.

Access lists are used in a variety of features. If your feature uses Modular Policy Framework, you can use an access list to identify traffic within a traffic class map. For more information on Modular Policy Framework, see [Chapter 30, “Configuring a Service Policy Using the Modular Policy Framework.”](#)

This chapter includes the following sections:

- [Access List Types, page 12-1](#)
- [Access Control Entry Order, page 12-2](#)
- [Access Control Implicit Deny, page 12-3](#)
- [IP Addresses Used for Access Lists When You Use NAT, page 12-3](#)
- [Where to Go Next, page 12-3](#)

## Access List Types

The adaptive security appliance uses five types of access control lists:

- Standard access lists—Identify the destination IP addresses of OSPF routes and can be used in a route map for OSPF redistribution. Standard access lists cannot be applied to interfaces to control traffic. For more information, see [Chapter 15, “Adding a Standard Access List.”](#)
- Extended access lists—Use one or more access control entries (ACE) in which you can specify the line number to insert the ACE, the source and destination addresses, and, depending upon the ACE type, the protocol, the ports (for TCP or UDP), or the ICMP type (for ICMP). For more information, see [Chapter 13, “Adding an Extended Access List.”](#)
- EtherType access lists—Use one or more ACEs that specify an EtherType. For more information, see [Chapter 14, “Adding an EtherType Access List.”](#)
- Webtype access lists—Used in a configuration that supports filtering for clientless SSL VPN. For more information, see [Chapter 16, “Adding a Webtype Access List.”](#)

- IPv6 access lists—Determine which IPv6 traffic to block and which traffic to forward at router interfaces. For more information, see [Chapter 17, “Adding an IPv6 Access List.”](#)

[Table 12-1](#) lists the types of access lists and some common uses for them.

**Table 12-1** *Access List Types and Common Uses*

Access List Use	Access List Type	Description
Control network access for IP traffic (routed and transparent mode)	Extended	The adaptive security appliance does not allow any traffic from a lower security interface to a higher security interface unless it is explicitly permitted by an extended access list.  <b>Note</b> To access the adaptive security appliance interface for management access, you do not also need an access list allowing the host IP address. You only need to configure management access according to <a href="#">Chapter 34, “Configuring Management Access.”</a>
Identify traffic for AAA rules	Extended	AAA rules use access lists to identify traffic.
Control network access for IP traffic for a given user	Extended, downloaded from a AAA server per user	You can configure the RADIUS server to download a dynamic access list to be applied to the user, or the server can send the name of an access list that you already configured on the adaptive security appliance.
Identify addresses for NAT (policy NAT and NAT exemption)	Extended	Policy NAT lets you identify local traffic for address translation by specifying the source and destination addresses in an extended access list.
Establish VPN access	Extended	You can use an extended access list in VPN commands.
Identify traffic in a traffic class map for Modular Policy Framework	Extended EtherType	Access lists can be used to identify traffic in a class map, which is used for features that support Modular Policy Framework. Features that support Modular Policy Framework include TCP and general connection settings, and inspection.
For transparent firewall mode, control network access for non-IP traffic	EtherType	You can configure an access list that controls traffic based on its EtherType.
Identify OSPF route redistribution	Standard	Standard access lists include only the destination address. You can use a standard access list to control the redistribution of OSPF routes.
Filtering for WebVPN	Webtype	You can configure a Webtype access list to filter URLs.
Control network access for IPV6 networks	IPv6	You can add and apply access lists to control traffic in IPv6 networks.

## Access Control Entry Order

An access list is made up of one or more access control entries (ACEs). Each ACE that you enter for a given access list name is appended to the end of the access list. Depending on the access list type, you can specify the source and destination addresses, the protocol, the ports (for TCP or UDP), the ICMP type (for ICMP), or the EtherType.

The order of ACEs is important. When the adaptive security appliance decides whether to forward or to drop a packet, the adaptive security appliance tests the packet against each ACE in the order in which the entries are listed. After a match is found, no more ACEs are checked. For example, if you create an ACE at the beginning of an access list that explicitly permits all traffic, no further statements are checked, and the packet is forwarded.

## Access Control Implicit Deny

All access lists (except Extended access lists) have an implicit deny statement at the end, so unless you explicitly permit traffic to pass, it will be denied. For example, if you want to allow all users to access a network through the adaptive security appliance except for one or more particular addresses, then you need to deny those particular addresses and then permit all others.

For EtherType access lists, the implicit deny at the end of the access list does not affect IP traffic or ARPs; for example, if you allow EtherType 8037, the implicit deny at the end of the access list does not now block any IP traffic that you previously allowed with an extended access list (or implicitly allowed from a high security interface to a low security interface). However, if you *explicitly* deny all traffic with an EtherType ACE, then IP and ARP traffic is denied.

## IP Addresses Used for Access Lists When You Use NAT

For the following features, you should always use the *real* IP address in the access list when you use NAT, even if the address as seen on an interface is the mapped address:

- **access-group** command
- Modular Policy Framework **match access-list** command
- Botnet Traffic Filter **dynamic-filter enable classify-list** command
- AAA **aaa ... match** commands
- WCCP **wccp redirect-list group-list** command

The following features use access lists, but these access lists use the *mapped* values as seen on an interface:

- IPSec access lists
- capture command access lists
- Per-user access lists
- Routing protocols
- All other features...

## Where to Go Next

For information about implementing access lists, see the following chapters in this guide:

- [Chapter 13, “Adding an Extended Access List”](#)
- [Chapter 14, “Adding an EtherType Access List”](#)

- [Chapter 15, “Adding a Standard Access List”](#)
- [Chapter 16, “Adding a Webtype Access List”](#)
- [Chapter 17, “Adding an IPv6 Access List”](#)
- [Chapter 32, “Configuring Access Rules”](#)

# CHAPTER 13

## Adding an Extended Access List

This chapter describes how to configure extended access lists (also known as access control lists), and it includes the following sections:

- [Information About Extended Access Lists, page 13-1](#)
- [Licensing Requirements for Extended Access Lists, page 13-1](#)
- [Guidelines and Limitations, page 13-2](#)
- [Default Settings, page 13-2](#)
- [Configuring Extended Access Lists, page 13-3](#)
- [Monitoring Extended Access Lists, page 13-5](#)
- [Configuration Examples for Extended Access Lists, page 13-5](#)
- [Where to Go Next, page 13-7](#)
- [Feature History for Extended Access Lists, page 13-7](#)

## Information About Extended Access Lists

Access lists are used to control network access or to specify traffic for many features to act upon. An extended access list is made up of one or more access control entries (ACE) in which you can specify the line number to insert the ACE, the source and destination addresses, and, depending upon the ACE type, the protocol, the ports (for TCP or UDP), or the ICMP type. You can identify all of these parameters within the **access-list** command, or you can use objects for each parameter.

You can identify all of these parameters by creating an access list, or you can use object groups and service groups for each parameter. (For more information about network objects and service objects, see the [“Configuring Objects and Groups”](#) section on page 11-1.)

## Licensing Requirements for Extended Access Lists

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

# Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

## Context Mode Guidelines

Supported in single and multiple context mode.

## Firewall Mode Guidelines

Supported only in routed and transparent firewall modes.

## IPv6 Guidelines

IPv6 is supported.

## Additional Guidelines and Limitations

The following guidelines and limitations apply to creating an extended access list:

- Enter the access list name in uppercase letters so that the name is easy to see in the configuration. You might want to name the access list for the interface (for example, INSIDE), or you can name it for the purpose for which it is created (for example, NO\_NAT or VPN).
- You can specify the source and destination ports only for the TCP or UDP protocols. For a list of permitted keywords and well-known port assignments, see the [“TCP and UDP Ports” section on page B-11](#). DNS, Discard, Echo, Ident, NTP, RPC, SUNRPC, and Talk each require one definition for TCP and one for UDP. TACACS+ requires one definition for port 49 on TCP.
- Typically, you identify the **ip** keyword for the protocol, but other protocols are accepted. For a list of protocol names, see the [“Protocols and Applications” section on page B-11](#).
- When you specify a network mask, the method is different from the Cisco IOS software **access-list** command. The adaptive security appliance uses a network mask (for example, 255.255.255.0 for a Class C mask). The Cisco IOS mask uses wildcard bits (for example, 0.0.0.255).

# Default Settings

[Table 13-1](#) lists the default settings for extended access list parameters.

**Table 13-1** Default Extended Access List Parameters

Parameters	Default
ACE logging	ACE logging generates system log message 106023 for denied packets. A deny ACE must be present to log denied packets.
log	When the <b>log</b> keyword is specified, the default level for system log message 106100 is 6 (informational), and the default interval is 300 seconds.

# Configuring Extended Access Lists

This section shows how to add and delete an access control entry and access list, and it includes the following topics:

- [Adding an Extended Access List, page 13-3](#)
- [Adding Remarks to Access Lists, page 13-5](#)

## Adding an Extended Access List

An access list is made up of one or more access control entries (ACEs) with the same access list ID. To create an access list you start by creating an ACE and applying a list name. An access list with one entry is still considered a list, although you can add multiple entries to the list.

### Prerequisites

(Optional) Create an object or an object group according to the [“Configuring Objects and Groups” section on page 11-1](#).

### Guidelines

To delete an ACE, enter the **no access-list** command with the entire command syntax string as it appears in the configuration. To remove the entire access list, use the **clear configure access-list** command.

## Detailed Steps

Command	Purpose
<p>(For IP traffic, no ports)</p> <pre>access-list access_list_name [line line_number] extended {deny   permit} {protocol   object-group prot_grp_id} {source_address mask   object nw_obj_id   object-group nw_grp_id} {dest_address mask   object nw_obj_id   object-group nw_grp_id} [log [[level] [interval secs]   disable   default]] [inactive   time-range time_range_name]</pre> <p>(For TCP or UDP traffic, with ports)</p> <pre>access-list access_list_name [line line_number] extended {deny   permit} {tcp   udp   object-group prot_grp_id} {source_address mask   object nw_obj_id   object-group nw_grp_id} [operator port   object-group svc_grp_id] {dest_address mask   object nw_obj_id   object-group nw_grp_id} [operator port   object-group svc_grp_id] [log [[level] [interval secs]   disable   default]] [inactive   time-range time_range_name]</pre> <p>(For ICMP traffic)</p> <pre>access-list access_list_name [line line_number] extended {deny   permit} icmp {source_address mask   object nw_obj_id   object-group nw_grp_id} {dest_address mask   object nw_obj_id   object-group nw_grp_id} [icmp_type   object-group icmp_grp_id] [log [[level] [interval secs]   disable   default]] [inactive   time-range time_range_name]</pre> <p><b>Example:</b></p> <pre>hostname(config)# access-list ACL_IN extended permit ip any any</pre>	<p>Adds an extended ACE.</p> <p>The <b>line</b> <i>line_number</i> option specifies the line number at which insert the ACE. If you do not specify a line number, the ACE is added to the end of the access list. The line number is not saved in the configuration; it only specifies where to insert the ACE.</p> <p>The <b>deny</b> keyword denies a packet if the conditions are matched. The <b>permit</b> keyword permits a packet if the conditions are matched.</p> <p>Instead of entering the protocol, IP address, or port directly in the command, you can use network objects, or protocol, network, port, or ICMP object groups using the <b>object</b> and <b>object-group</b> keyword. See <a href="#">“Configuring Objects and Groups” section on page 11-1</a> for more information about creating objects.</p> <p>The <i>protocol</i> argument specifies the IP protocol name or number. For example UDP is 17, TCP is 6, and EGP is 47.</p> <p>The <i>source_address</i> specifies the IP address of the network or host from which the packet is being sent. Enter the <b>host</b> keyword before the IP address to specify a single address. In this case, do not enter a mask. Enter the <b>any</b> keyword instead of the address and mask to specify any address.</p> <p>For the TCP and UDP protocols only, the <i>operator port</i> option matches the port numbers used by the source or destination. The permitted operators are as follows:</p> <ul style="list-style-type: none"> <li>• <b>lt</b>—less than.</li> <li>• <b>gt</b>—greater than.</li> <li>• <b>dq</b>—equal to.</li> <li>• <b>neq</b>—not equal to.</li> <li>• <b>range</b>—an inclusive range of values. When you use this operator, specify two port numbers, for example: <b>range 100 200</b>.</li> </ul> <p>The <i>dest_address</i> argument specifies the IP address of the network or host to which the packet is being sent. Enter the <b>host</b> keyword before the IP address to specify a single address. In this case, do not enter a mask. Enter the <b>any</b> keyword instead of the address and mask to specify any address.</p> <p>The <i>icmp_type</i> argument specifies the ICMP type if the protocol is ICMP.</p> <p>The <b>time-range</b> keyword specifies when an access list is activated. See the <a href="#">“Scheduling Extended Access List Activation” section on page 11-16</a> for more information.</p> <p>The <b>inactive</b> keyword disables an ACE. To reenble it, enter the entire ACE without the <b>inactive</b> keyword. This feature enables you to keep a record of an inactive ACE in your configuration to make reenabling easier.</p> <p>For the <b>log</b> keyword, see <a href="#">Chapter 18, “Configuring Logging for Access Lists.”</a></p>

## Adding Remarks to Access Lists

You can include remarks about entries in any access list, including extended, EtherType, IPv6, standard, and Webtype access lists. The remarks make the access list easier to understand.

To add a remark after the last **access-list** command you entered, enter the following command:

Command	Purpose
<b>access-list</b> <i>access_list_name</i> <b>remark</b> <i>text</i>	Adds a remark after the last access-list command you entered.
<b>Example:</b> hostname(config)# access-list OUT remark - this is the inside admin address	The text can be up to 100 characters in length. You can enter leading spaces at the beginning of the text. Trailing spaces are ignored.  If you enter the remark before any <b>access-list</b> command, then the remark is the first line in the access list.  If you delete an access list using the <b>no access-list</b> <i>access_list_name</i> command, then all the remarks are also removed.

### Example

You can add remarks before each ACE, and the remark appears in the access list in this location. Entering a dash (-) at the beginning of the remark helps set it apart from the ACEs.

```
hostname(config)# access-list OUT remark - this is the inside admin address
hostname(config)# access-list OUT extended permit ip host 209.168.200.3 any
hostname(config)# access-list OUT remark - this is the hr admin address
hostname(config)# access-list OUT extended permit ip host 209.168.200.4 any
```

## Monitoring Extended Access Lists

To monitor extended access lists, enter one of the following commands:

Command	Purpose
<b>show access list</b>	Displays the access list entries by number.
<b>show running-config access-list</b>	Displays the current running access-list configuration.

## Configuration Examples for Extended Access Lists

This section includes the following topics:

- [Configuration Examples for Extended Access Lists \(No Objects\)](#), page 13-6
- [Configuration Examples for Extended Access Lists \(Using Objects\)](#), page 13-6

## Configuration Examples for Extended Access Lists (No Objects)

The following access list allows all hosts (on the interface to which you apply the access list) to go through the adaptive security appliance:

```
hostname(config)# access-list ACL_IN extended permit ip any any
```

The following sample access list prevents hosts on 192.168.1.0/24 from accessing the 209.165.201.0/27 network. All other addresses are permitted.

```
hostname(config)# access-list ACL_IN extended deny tcp 192.168.1.0 255.255.255.0
209.165.201.0 255.255.255.224
hostname(config)# access-list ACL_IN extended permit ip any any
```

If you want to restrict access to selected hosts only, then enter a limited permit ACE. By default, all other traffic is denied unless explicitly permitted.

```
hostname(config)# access-list ACL_IN extended permit ip 192.168.1.0 255.255.255.0
209.165.201.0 255.255.255.224
```

The following access list restricts all hosts (on the interface to which you apply the access list) from accessing a website at address 209.165.201.29. All other traffic is allowed.

```
hostname(config)# access-list ACL_IN extended deny tcp any host 209.165.201.29 eq www
hostname(config)# access-list ACL_IN extended permit ip any any
```

The following access list that uses object groups restricts several hosts on the inside network from accessing several web servers. All other traffic is allowed.

```
hostname(config-network)# access-list ACL_IN extended deny tcp object-group denied
object-group web eq www
hostname(config)# access-list ACL_IN extended permit ip any any
hostname(config)# access-group ACL_IN in interface inside
```

The following example temporarily disables an access list that permits traffic from one group of network objects (A) to another group of network objects (B):

```
hostname(config)# access-list 104 permit ip host object-group A object-group B inactive
```

To implement a time-based access list, use the **time-range** command to define specific times of the day and week. Then use the **access-list extended** command to bind the time range to an access list. The following example binds an access list named “Sales” to a time range named “New\_York\_Minute.”

```
hostname(config)# access-list Sales line 1 extended deny tcp host 209.165.200.225 host
209.165.201.1 time-range New_York_Minute
```

## Configuration Examples for Extended Access Lists (Using Objects)

The following normal access list that does not use object groups restricts several hosts on the inside network from accessing several web servers. All other traffic is allowed.

```
hostname(config)# access-list ACL_IN extended deny tcp host 10.1.1.4 host 209.165.201.29
eq www
hostname(config)# access-list ACL_IN extended deny tcp host 10.1.1.78 host 209.165.201.29
eq www
hostname(config)# access-list ACL_IN extended deny tcp host 10.1.1.89 host 209.165.201.29
eq www
hostname(config)# access-list ACL_IN extended deny tcp host 10.1.1.4 host 209.165.201.16
eq www
hostname(config)# access-list ACL_IN extended deny tcp host 10.1.1.78 host 209.165.201.16
eq www
```

```
hostname(config)# access-list ACL_IN extended deny tcp host 10.1.1.89 host 209.165.201.16
eq www
hostname(config)# access-list ACL_IN extended deny tcp host 10.1.1.4 host 209.165.201.78
eq www
hostname(config)# access-list ACL_IN extended deny tcp host 10.1.1.78 host 209.165.201.78
eq www
hostname(config)# access-list ACL_IN extended deny tcp host 10.1.1.89 host 209.165.201.78
eq www
hostname(config)# access-list ACL_IN extended permit ip any any
hostname(config)# access-group ACL_IN in interface inside
```

If you make two network object groups, one for the inside hosts, and one for the web servers, then the configuration can be simplified and can be easily modified to add more hosts:

```
hostname(config)# object-group network denied
hostname(config-network)# network-object host 10.1.1.4
hostname(config-network)# network-object host 10.1.1.78
hostname(config-network)# network-object host 10.1.1.89

hostname(config-network)# object-group network web
hostname(config-network)# network-object host 209.165.201.29
hostname(config-network)# network-object host 209.165.201.16
hostname(config-network)# network-object host 209.165.201.78

hostname(config-network)# access-list ACL_IN extended deny tcp object-group denied
object-group web eq www
hostname(config)# access-list ACL_IN extended permit ip any any
hostname(config)# access-group ACL_IN in interface inside
```

## Where to Go Next

Apply the access list to an interface. See the [“Configuring Access Rules” section on page 32-7](#) for more information.

## Feature History for Extended Access Lists

[Table 13-2](#) lists the release history for this feature.

**Table 13-2** Feature History for Extended Access Lists

Feature Name	Releases	Feature Information
Extended access lists	7.0(1)	Access lists are used to control network access or to specify traffic for many features to act upon. An extended access control list is made up of one or more access control entries (ACE) in which you can specify the line number to insert the ACE, the source and destination addresses, and, depending upon the ACE type, the protocol, the ports (for TCP or UDP), or the ICMP type (for ICMP).  The following command was introduced: <b>access-list extended</b> .

# CHAPTER 14

## Adding an EtherType Access List

This chapter describes how to configure EtherType access lists and includes the following sections:

- [Information About EtherType Access Lists, page 14-1](#)
- [Licensing Requirements for EtherType Access Lists, page 14-1](#)
- [Guidelines and Limitations, page 14-2](#)
- [Default Settings, page 14-2](#)
- [Configuring EtherType Access Lists, page 14-2](#)
- [Monitoring EtherType Access Lists, page 14-4](#)
- [What to Do Next, page 14-4](#)
- [Configuration Examples for EtherType Access Lists, page 14-5](#)
- [Feature History for EtherType Access Lists, page 14-5](#)

### Information About EtherType Access Lists

An EtherType access list is made up of one or more Access Control Entries (ACEs) that specify an EtherType. An EtherType rule controls any EtherType identified by a 16-bit hexadecimal number.

For information about creating an access rule with the EtherType access list, see [Chapter 32, “Configuring Access Rules.”](#)

### Licensing Requirements for EtherType Access Lists

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

# Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

## Context Mode Guidelines

Available in single and multiple context modes.

## Firewall Mode Guidelines

Supported in transparent firewall mode only.

## IPv6 Guidelines

Supports IPv6.

## Additional Guidelines and Limitations

The following guidelines and limitations apply to EtherType access lists:

- For EtherType access lists, the implicit deny at the end of the access list does not affect IP traffic or ARPs; for example, if you allow EtherType 8037, the implicit deny at the end of the access list does not now block any IP traffic that you previously allowed with an extended access list (or implicitly allowed from a high security interface to a low security interface). However, if you *explicitly* deny all traffic with an EtherType ACE, then IP and ARP traffic is denied.
- EtherType access lists support Ethernet V2 frames.
- 802.3-formatted frames are not handled by the access list because they use a length field as opposed to a type field. Bridge protocol data units, which are allowed by default, are the only exception; they are SNAP-encapsulated, and the adaptive security appliance is designed to specifically handle BPDUs.

## Default Settings

Access list logging generates system log message 106023 for denied packets. Deny packets must be present to log denied packets.

When you configure logging for the access list, the default severity level for system log message 106100 is 6 (informational).

## Configuring EtherType Access Lists

This section includes the following topics:

- [Task Flow for Configuring EtherType Access Lists, page 14-2](#)
- [Adding EtherType Access Lists, page 14-3](#)
- [Adding Remarks to Access Lists, page 14-4](#)

## Task Flow for Configuring EtherType Access Lists

Use the following guidelines to create and implement an access list:

- Step 1** Create an access list by adding an ACE and applying an access list name, as shown in the “[Adding EtherType Access Lists](#)” section on page 14-3.
- Step 2** Apply the access list to an interface. (See the “[Configuring Access Rules](#)” section on page 32-7 for more information.)

## Adding EtherType Access Lists

To configure an access list that controls traffic based upon its EtherType, perform the following steps.

### Detailed Steps

Command	Purpose
<pre>access-list access_list_name ethertype {deny   permit} {ipx   bpdud   mpls-unicast   mpls-multicast   any   hex_number}</pre> <p><b>Example:</b></p> <pre>hostname(config)# hostname(config)# access-list ETHER ethertype permit ipx</pre>	<p>Adds an EtherType ACE.</p> <p>The <i>access_list_name</i> argument lists the name or number of an access list. When you specify an access list name, the ACE is added to the end of the access list. Enter the <i>access_list_name</i> in upper case letters so that the name is easy to see in the configuration. You might want to name the access list for the interface (for example, INSIDE) or for the purpose (for example, MPLS or PIX).</p> <p>The <b>any</b> keyword specifies access to anyone.</p> <p>The <b>bpdud</b> keyword specifies access to bridge protocol data units, which are permitted by default.</p> <p>The <b>deny</b> keyword denies access if the conditions are matched. If an EtherType access list is configured to deny all, all ethernet frames are discarded. Only physical protocol traffic, such as auto-negotiation, is still allowed.</p> <p>The <i>hex_number</i> argument indicates any EtherType that can be identified by a 16-bit hexadecimal number greater than or equal to 0x600. (See RFC 1700, “Assigned Numbers,” at <a href="http://www.ietf.org/rfc/rfc1700.txt">http://www.ietf.org/rfc/rfc1700.txt</a> for a list of EtherTypes.)</p> <p>The <b>ipx</b> keyword specifies access to IPX.</p> <p>The <b>mpls-multicast</b> keyword specifies access to MPLS multicast.</p> <p>The <b>mpls-unicast</b> keyword specifies access to MPLS unicast.</p> <p>The <b>permit</b> keyword permits access if the conditions are matched.</p> <p> <b>Note</b> To remove an EtherType ACE, enter the <b>no access-list</b> command with the entire command syntax string as it appears in the configuration.</p>

### Example

The following sample access list allows common EtherTypes originating on the inside interface:

```
hostname(config)# access-list ETHER ethertype permit ipx
hostname(config)# access-list ETHER ethertype permit mpls-unicast
hostname(config)# access-group ETHER in interface inside
```

## Adding Remarks to Access Lists

You can include remarks about entries in any access list, including extended, EtherType, IPv6, standard, and Webtype access lists. The remarks make an access list easier to understand.

To add a remark after the last **access-list** command you entered, enter the following command:

Command	Purpose
<b>access-list</b> <i>access_list_name</i> <b>remark</b> <i>text</i>	Adds a remark after the last <b>access-list</b> command you entered.
<b>Example:</b> hostname(config)# access-list OUT remark - this is the inside admin address	<p>The text can be up to 100 characters in length. You can enter leading spaces at the beginning of the text. Trailing spaces are ignored.</p> <p>If you enter the remark before any <b>access-list</b> command, then the remark is the first line in the access list.</p> <p>If you delete an access list using the <b>no access-list</b> <i>access_list_name</i> command, then all remarks are also removed.</p>

### Example

You can add remarks before each ACE, and the remarks appear in the access list in these locations. Entering a dash (-) at the beginning of a remark helps to set it apart from the ACE.

```
hostname(config)# access-list OUT remark - this is the inside admin address
hostname(config)# access-list OUT extended permit ip host 209.168.200.3 any
hostname(config)# access-list OUT remark - this is the hr admin address
hostname(config)# access-list OUT extended permit ip host 209.168.200.4 any
```

## What to Do Next

Apply the access list to an interface. (See the [“Configuring Access Rules”](#) section on page 32-7 for more information.)

## Monitoring EtherType Access Lists

To monitor EtherType access lists, enter one of the following commands:

Command	Purpose
<b>show access-list</b>	Displays the access list entries by number.
<b>show running-config access-list</b>	Displays the current running access-list configuration.

# Configuration Examples for EtherType Access Lists

The following example shows how to configure EtherType access lists:

The following access list allows some EtherTypes through the adaptive security appliance, but it denies IPX:

```
hostname(config)# access-list ETHER ethertype deny ipx
hostname(config)# access-list ETHER ethertype permit 0x1234
hostname(config)# access-list ETHER ethertype permit mpls-unicast
hostname(config)# access-group ETHER in interface inside
hostname(config)# access-group ETHER in interface outside
```

The following access list denies traffic with EtherType 0x1256, but it allows all others on both interfaces:

```
hostname(config)# access-list nonIP ethertype deny 1256
hostname(config)# access-list nonIP ethertype permit any
hostname(config)# access-group ETHER in interface inside
hostname(config)# access-group ETHER in interface outside
```

## Feature History for EtherType Access Lists

Table 14-1 lists the release history for this feature.

**Table 14-1** Feature History for EtherType Access Lists

Feature Name	Releases	Feature Information
EtherType access lists	7.0	EtherType access lists control traffic based upon its EtherType.  The feature and the following command were introduced: <b>access-list ethertype.</b>

# CHAPTER 15

## Adding a Standard Access List

This chapter describes how to configure a standard access list and includes the following sections:

- [Information About Standard Access Lists, page 15-1](#)
- [Licensing Requirements for Standard Access Lists, page 15-1](#)
- [Guidelines and Limitations, page 15-1](#)
- [Default Settings, page 15-2](#)
- [Adding Standard Access Lists, page 15-3](#)
- [What to Do Next, page 15-4](#)
- [Monitoring Access Lists, page 15-4](#)
- [Configuration Examples for Standard Access Lists, page 15-5](#)
- [Feature History for Standard Access Lists, page 15-5](#)

## Information About Standard Access Lists

Standard access lists identify the destination IP addresses of OSPF routes and can be used in a route map for OSPF redistribution. Standard access lists cannot be applied to interfaces to control traffic.

## Licensing Requirements for Standard Access Lists

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature:

- [Context Mode Guidelines, page 15-2](#)
- [Firewall Mode Guidelines, page 15-2](#)

- [IPv6 Guidelines, page 15-2](#)
- [Additional Guidelines and Limitations, page 15-2](#)

**Context Mode Guidelines**

Supported in single context mode only.

**Firewall Mode Guidelines**

Supported in routed and transparent firewall modes.

**IPv6 Guidelines**

Supports IPv6.

**Additional Guidelines and Limitations**

The following guidelines and limitations apply for standard Access Lists:

- Standard ACLs identify the destination IP addresses (not source addresses) of OSPF routes and can be used in a route map for OSPF redistribution. Standard ACLs cannot be applied to interfaces to control traffic.
- To add additional ACEs at the end of the access list, enter another **access-list** command, specifying the same access list name.
- When used with the **access-group** command, the **deny** keyword does not allow a packet to traverse the adaptive security appliance. By default, the adaptive security appliance denies all packets on the originating interface unless you specifically permit access.
- When specifying a source, local, or destination address, use the following guidelines:
  - Use a 32-bit quantity in four-part, dotted-decimal format.
  - Use the keyword **any** as an abbreviation for an address and mask of 0.0.0.0.0.0.0.
  - Use the **host ip\_address** option as an abbreviation for a mask of 255.255.255.255.
- You can disable an ACE by specifying the keyword **inactive** in the **access-list** command.

# Default Settings

[Table 15-1](#) lists the default settings for standard Access List parameters.

**Table 15-1      Default Standard Access List Parameters**

Parameters	Default
deny	<p>The adaptive security appliance denies all packets on the originating interface unless you specifically permit access.</p> <p>Access list logging generates system log message 106023 for denied packets. Deny packets must be present to log denied packets.</p>

# Adding Standard Access Lists

This section includes the following topics:

- [Task Flow for Configuring Extended Access Lists, page 15-3](#)
- [Adding a Standard Access List, page 15-3](#)
- [Adding Remarks to Access Lists, page 15-4](#)

## Task Flow for Configuring Extended Access Lists

Use the following guidelines to create and implement an access list:

- Create an access list by adding an ACE and applying an access list name. See in the [“Adding Standard Access Lists” section on page 15-3](#).
- Apply the access list to an interface. See the [“Configuring Access Rules” section on page 32-7](#) for more information.

## Adding a Standard Access List

To add an access list to identify the destination IP addresses of OSPF routes, which can be used in a route map for OSPF redistribution, enter the following command:

Command	Purpose
<pre>hostname(config)# <b>access-list</b> access_list_name <b>standard</b> {<b>deny</b>   <b>permit</b>} {<b>any</b>   ip_address mask}</pre> <p><b>Example:</b></p> <pre>hostname(config)# access-list OSPF standard permit 192.168.1.0 255.255.255.0</pre>	<p>Adds a standard access list entry. To add another ACE to the end of the access list, enter another <b>access-list</b> command, specifying the same access list name.</p> <p>The <i>access_list_name</i> argument specifies the name of number of an access list.</p> <p>The <b>any</b> keyword specifies access to anyone.</p> <p>The <b>deny</b> keyword denies access if the conditions are matched.</p> <p>The <b>host ip_address</b> syntax specifies access to a host IP address.</p> <p>The <i>ip_address ip_mask</i> argument specifies access to a specific IP address and subnet mask.</p> <p>The <b>line line-num</b> option specifies the line number at which to insert an ACE.</p> <p>The <b>permit</b> keyword permits access if the conditions are matched.</p> <p>To remove an ACE, enter the <b>no access-list</b> command with the entire command syntax string as it appears in the configuration.</p>

### Step 1

# Adding Remarks to Access Lists

You can include remarks about entries in any access list, including extended, EtherType, IPv6, standard, and Webtype access lists. The remarks make the access list easier to understand.

To add a remark after the last **access-list** command you entered, enter the following command:

Command	Purpose
<b>access-list</b> <i>access_list_name</i> <b>remark</b> <i>text</i>	Adds a remark after the last <b>access-list</b> command you entered.
<b>Example:</b> hostname(config)# <b>access-list</b> OUT remark - this is the inside admin address	<p>The text can be up to 100 characters in length. You can enter leading spaces at the beginning of the text. Trailing spaces are ignored.</p> <p>If you enter the remark before any <b>access-list</b> command, then the remark is the first line in the access list.</p> <p>If you delete an access list using the <b>no access-list</b> <i>access_list_name</i> command, then all the remarks are also removed.</p>

## Example

You can add a remark before each ACE, and the remarks appear in the access lists in these location. Entering a dash (-) at the beginning of a remark helps to set it apart from an ACE.

```
hostname(config)# access-list OUT remark - this is the inside admin address
hostname(config)# access-list OUT extended permit ip host 209.168.200.3 any
hostname(config)# access-list OUT remark - this is the hr admin address
hostname(config)# access-list OUT extended permit ip host 209.168.200.4 any
```

# What to Do Next

Apply the access list to an interface. See the [“Configuring Access Rules” section on page 32-7](#) for more information.

# Monitoring Access Lists

To monitor access lists, perform one of the following tasks:

Command	Purpose
<b>show access-list</b>	Displays the access list entries by number.
<b>show running-config access-list</b>	Displays the current running access-list configuration.

# Configuration Examples for Standard Access Lists

The following example shows how to deny IP traffic through the adaptive security appliance:

```
hostname(config)# access-list 77 standard deny
```

The following example shows how to permit IP traffic through the adaptive security appliance if conditions are matched:

```
hostname(config)# access-list 77 standard permit
```

The following example shows how to specify a destination address:

```
hostname(config)# access-list 77 standard permit host 10.1.10.123
```

## Feature History for Standard Access Lists

[Table 15-2](#) lists the release history for this feature.

**Table 15-2** Feature History for Standard Access Lists

Feature Name	Releases	Feature Information
Standard access lists	7.0	Standard access lists identify the destination IP addresses of OSPF routes, which can be used in a route map for OSPF redistribution.  The feature and the following command were introduced: <b>access-list standard.</b>

# CHAPTER 16

## Adding a Webtype Access List

Webtype access lists are added to a configuration that supports filtering for clientless SSL VPN. This chapter describes how to add an access list to the configuration that supports filtering for WebVPN.

This chapter includes the following sections:

- [Licensing Requirements for Webtype Access Lists, page 16-1](#)
- [Guidelines and Limitations, page 16-1](#)
- [Default Settings, page 16-2](#)
- [Using Webtype Access Lists, page 16-2](#)
- [Monitoring Webtype Access Lists, page 16-5](#)
- [Configuration Examples for Webtype Access Lists, page 16-6](#)
- [Feature History for Webtype Access Lists, page 16-7](#)

## Licensing Requirements for Webtype Access Lists

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature:

- [Context Mode Guidelines, page 16-1](#)
- [Firewall Mode Guidelines, page 16-2](#)
- [Additional Guidelines and Limitations, page 16-2](#)

### Context Mode Guidelines

Supported in single and multiple context mode.

**Firewall Mode Guidelines**

Supported in routed and transparent firewall mode.

**IPv6 Guidelines**

Supports IPv6.

**Additional Guidelines and Limitations**

The following guidelines and limitations apply to Webtype access lists:

- The **access-list webtype** command is used to configure clientless SSL VPN filtering. The URL specified may be full or partial (no file specified), may include wildcards for the server, or may specify a port. See the [“Adding Webtype Access Lists with a URL String” section on page 16-3](#) for information about using wildcard characters in the URL string.
- Valid protocol identifiers are http, https, cifs, imap4, pop3, and smtp. The RL may also contain the keyword **any** to refer to any URL. An asterisk may be used to refer to a subcomponent of a DNS name.
- 

## Default Settings

[Table 16-1](#) lists the default settings for Webtype access lists parameters.

**Table 16-1**      *Default Webtype Access List Parameters*

Parameters	Default
deny	The adaptive security appliance denies all packets on the originating interface unless you specifically permit access.
log	Access list logging generates system log message 106023 for denied packets. Deny packets must be present to log denied packets.

## Using Webtype Access Lists

This section includes the following topics:

- [Task Flow for Configuring Webtype Access Lists, page 16-2](#)

### Task Flow for Configuring Webtype Access Lists

Use the following guidelines to create and implement an access list:

- Create an access list by adding an ACE and applying an access list name. See the [“Using Webtype Access Lists” section on page 16-2](#).
- Apply the access list to an interface. See the [“Configuring Access Rules” section on page 32-7](#) for more information.

## Adding Webtype Access Lists with a URL String

To add an access list to the configuration that supports filtering for clientless SSL VPN, enter the following command:

Command	Purpose
<pre>access-list access_list_name webtype {deny   permit} url [url_string   any] [log[[disable   default]   level] interval secs] [time_range name]]</pre> <p><b>Example:</b></p> <pre>hostname(config)# access-list acl_company webtype deny url http://*.company.com</pre>	<p>Adds an access list to the configuration that supports filtering for WebVPN.</p> <p>The <i>access_list_name</i> argument specifies the name or number of an access list.</p> <p>The <b>any</b> keyword specifies all URLs.</p> <p>The <b>deny</b> keyword denies access if the conditions are matched.</p> <p>The <b>interval</b> option specifies the time interval at which to generate system log message 106100; valid values are from 1 to 600 seconds.</p> <p>The <b>log</b> [[<b>disable</b>   <b>default</b>]   <i>level</i>] option specifies that system log message 106100 is generated for the ACE. When the log optional keyword is specified, the default level for system log message 106100 is 6 (informational). See the <b>log</b> command for more information.</p> <p>The <b>permit</b> keyword permits access if the conditions are matched.</p> <p>The <b>time_range</b> <i>name</i> option specifies a keyword for attaching the time-range option to this access list element.</p> <p>The <b>url</b> keyword specifies that a URL be used for filtering.</p> <p>The <i>url_string</i> option specifies the URL to be filtered.</p> <p>You can use the following wildcard characters to define more than one wildcard in the Webtype access list entry:</p> <ul style="list-style-type: none"> <li>• Enter an asterisk “*” to match no characters or any number of characters.</li> <li>• Enter a question mark “?” to match any one character exactly.</li> <li>• Enter square brackets “[ ]” to create a range operator that matches any one character in a range.</li> </ul> <p> <b>Note</b> To match any http URL, you must enter <b>http://*/*</b> instead of the former method of entering <b>http://*</b>.</p> <p>To remove an access list, use the <b>no</b> form of this command with the complete syntax string as it appears in the configuration.</p>

# Adding Webtype Access Lists with an IP Address

To add an access list to the configuration that supports filtering for clientless SSL VPN, enter the following command:

Command	Purpose
<pre>access-list access_list_name webtype {deny   permit} tcp [host ip_address   ip_address subnet_mask   any] [oper port[port]] [log[[disable   default]   level] interval secs][time_range name]]</pre>	<p>Adds an access list to the configuration that supports filtering for WebVPN.</p> <p>The <i>access_list_name</i> argument specifies the name or number of an access list.</p> <p>The <b>any</b> keyword specifies all IP addresses.</p> <p>The <b>deny</b> keyword denies access if the conditions are matched.</p> <p>The <b>host ip_address</b> option specifies a host IP address.</p> <p>The <b>interval</b> option specifies the time interval at which to generate system log message 106100; valid values are from 1 to 600 seconds.</p> <p>The <i>ip_address ip_mask</i> option specifies a specific IP address and subnet mask.</p> <p>The <b>log [[disable   default]   level]</b> option specifies that system log message 106100 is generated for the ACE. When the log optional keyword is specified, the default level for system log message 106100 is 6 (informational). See the <b>log</b> command for more information.</p> <p>The <b>permit</b> keyword permits access if the conditions are matched.</p> <p>The <b>port</b> option specifies the decimal number or name of a TCP or UDP port.</p> <p>The <b>time_range name</b> option specifies a keyword for attaching the time-range option to this access list element.</p> <p>To remove an access list, use the <b>no</b> form of this command with the complete syntax string as it appears in the configuration.</p>
<p><b>Example:</b></p> <pre>hostname(config)# access-list acl_company webtype permit tcp any</pre>	

## Adding Remarks to Access Lists

You can include remarks about entries in any access list, including extended, EtherType, IPv6, standard, and Webtype access lists. The remarks make the access list easier to understand.

To add a remark after the last **access-list** command you entered, enter the following command:

Command	Purpose
<b>access-list</b> <i>access_list_name</i> <b>remark</b> <i>text</i>	Adds a remark after the last access-list command you entered.
<b>Example:</b> hostname(config)# access-list OUT remark - this is the inside admin address	The text can be up to 100 characters in length. You can enter leading spaces at the beginning of the text. Trailing spaces are ignored.  If you enter the remark before any <b>access-list</b> command, then the remark is the first line in the access list.  If you delete an access list using the <b>no access-list</b> <i>access_list_name</i> command, then all the remarks are also removed.

### Example

You can add a remark before each ACE, and the remarks appear in the access list in these locations. Entering a dash (-) at the beginning of a remark helps set it apart from an ACE.

```
hostname(config)# access-list OUT remark - this is the inside admin address
hostname(config)# access-list OUT extended permit ip host 209.168.200.3 any
hostname(config)# access-list OUT remark - this is the hr admin address
hostname(config)# access-list OUT extended permit ip host 209.168.200.4 any
```

#### Step 1

## What to Do Next

Apply the access list to an interface. See the [“Configuring Access Rules” section on page 32-7](#) for more information.

## Monitoring Webtype Access Lists

To monitor webtype access lists, enter the following command:

Command	Purpose
<b>show running-config access list</b>	Displays the access-list configuration running on the adaptive security appliance.

# Configuration Examples for Webtype Access Lists

The following example shows how to deny access to a specific company URL:

```
hostname(config)# access-list acl_company webtype deny url http://*.example.com
```

The following example shows how to deny access to a specific file:

```
hostname(config)# access-list acl_file webtype deny url
https://www.example.com/dir/file.html
```

The following example shows how to deny HTTP access to any URL through port 8080:

```
hostname(config)# access-list acl_company webtype deny url http://my-server:8080/*
```

The following examples show how to use wildcards in Webtype access lists.

- The following example matches URLs such as <http://www.example.com/> and <http://www.sample.com/>:

```
access-list test webtype permit url http://www.*ample/
```

- The following example matches URLs such as <http://www.cisco.com> and <ftp://wwwz.carrier.com>:

```
access-list test webtype permit url *://ww?.c*co*/
```

- The following example matches URLs such as <http://www.cisco.com:80> and <https://www.cisco.com:81>:

```
access-list test webtype permit url *://ww?.c*co*:8[01]/
```

The range operator “[ ] ” in the preceding example specifies that either character **0** or **1** can occur.

- The following example matches URLs such as <http://www.google.com> and <http://www.boogie.com>:

```
access-list test webtype permit url http://www.[a-z]oo?*/
```

The range operator “[ ] ” in the preceding example specifies that any character in the range from **a** to **z** can occur.

- The following example matches URLs such as <http://www.cisco.com/anything/crazy/url/ddtscgiz>:

```
access-list test webtype permit url htt*://**/*cgi*
```

## Note

To match any http URL, you must enter **http://\*\*/\*** instead of the former method of entering **http://\***.

The following example shows how to enforce a webtype access list to disable access to specific CIFS shares.

In this scenario we have a root folder named “shares” that contains two sub-folders named “Marketing\_Reports” and “Sales\_Reports.” We want to specifically deny access to the “shares/Marketing\_Reports” folder.

```
access-list CIFS_Avoid webtype deny url cifs://172.16.10.40/shares/Marketing_Reports.
```

However, due to the implicit “deny all,” the above access list makes all of the sub-folders inaccessible (“shares/Sales\_Reports” and “shares/Marketing\_Reports”), including the root folder (“shares”).

To fix the problem, add a new access list to allow access to the root folder and the remaining sub-folders:

```
access-list CIFS_Allow webtype permit url cifs://172.16.10.40/shares*
```

# Feature History for Webtype Access Lists

Table 16-2 lists the release history for this feature.

**Table 16-2**      *Feature History for Webtype Access Lists*

Feature Name	Releases	Feature Information
Webtype access lists	7.0	Webtype access lists are access lists that are added to a configuration that supports filtering for clientless SSL VPN.  The feature and the following command were introduced: <b>access-list webtype.</b>

# CHAPTER 17

## Adding an IPv6 Access List

This chapter describes how to configure IPv6 access lists to control and filter traffic through the adaptive security appliance.

This chapter includes the following sections:

- [Information About IPv6 Access Lists, page 17-1](#)
- [Licensing Requirements for IPv6 Access Lists, page 17-1](#)
- [Prerequisites for Adding IPv6 Access Lists, page 17-2](#)
- [Guidelines and Limitations, page 17-2](#)
- [Default Settings, page 17-3](#)
- [Configuring IPv6 Access Lists, page 17-4](#)
- [Monitoring IPv6 Access Lists, page 17-7](#)
- [Configuration Examples for IPv6 Access Lists, page 17-7](#)
- [Where to Go Next, page 17-7](#)
- [Feature History for IPv6 Access Lists, page 17-7](#)

## Information About IPv6 Access Lists

The typical access list functionality in IPv6 is similar to access lists in IPv4. Access lists determine which traffic to block and which traffic to forward at router interfaces. Access lists allow filtering based upon source and destination addresses, inbound and outbound to specific interfaces. Each access list has an implicit deny statement at the end. You define IPv6 access lists and set their deny and permit conditions using the **ipv6 access-list** command with the **deny** and **permit** keywords in global configuration mode.

## Licensing Requirements for IPv6 Access Lists

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

# Prerequisites for Adding IPv6 Access Lists

You should be familiar with IPv6 addressing and basic configuration. See the **ipv6** commands in the *Cisco Security Appliance Command Reference* for more information about configuring IPv6.

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context modes.

### Firewall Mode Guidelines

Supported in routed and transparent firewall modes.

### IPv6 Guidelines

Supports IPv6.

### Additional Guidelines and Limitations

The following guidelines and limitations apply to IPv6 access lists:

- The **ipv6 access-list** command allows you to specify whether an IPv6 address is permitted or denied access to a port or protocol. Each command is called an ACE. One or more ACEs with the same access list name are referred to as an access list. Apply an access list to an interface using the **access-group** command.
- The adaptive security appliance denies all packets from an outside interface to an inside interface unless you specifically permit access using an access list. All packets are allowed by default from an inside interface to an outside interface unless you specifically deny access.
- The **ipv6 access-list** command is similar to the **access-list** command, except that it is IPv6-specific. For additional information about access lists, refer to the **access-list extended** command.
- The **ipv6 access-list icmp** command is used to filter ICMPv6 messages that pass through the adaptive security appliance. To configure the ICMPv6 traffic that is allowed to originate and terminate at a specific interface, use the **ipv6 icmp** command.
- See the **object-group** command for information on how to configure object groups.
- Possible operands for the operator option of the **ipv6 access-list** command include **lt** for less than, **gt** for greater than, **eq** for equal to, **neq** for not equal to, and **range** for an inclusive range. Use the **ipv6 access-list** command without an operator and port to indicate all ports by default.
- ICMP message types are filtered by the access rule. Omitting the *icmp\_type* argument indicates all ICMP types. If you specify ICMP types, the value can be a valid ICMP type number (from 0 to 255) or one of the following ICMP type literals:
  - destination-unreachable
  - packet-too-big
  - time-exceeded
  - parameter-problem
  - echo-request

- echo-reply
  - membership-query
  - membership-report
  - membership-reduction
  - router-renumbering
  - router-solicitation
  - router-advertisement
  - neighbor-solicitation
  - neighbor-advertisement
  - neighbor-redirect
- If the protocol argument is specified, valid values are **icmp**, **ip**, **tcp**, **udp**, or an integer in the range of 1 to 254, representing an IP protocol number.

## Default Settings

Table 17-1 lists the default settings for IPv6 access list parameters.

**Table 17-1**      **Default IPv6 Access List Parameters**

Parameters	Default
<b>default</b>	The <b>default</b> option specifies that a syslog message 106100 is generated for the ACE.
<b>interval</b> <i>secs</i>	Specifies the time interval at which to generate a 106100 syslog message; valid values are from 1 to 600 seconds. The default interval is 300 seconds. This value is also used as the timeout value for deleting an inactive flow.
<i>level</i>	The <i>level</i> option specifies the syslog level for message 106100; valid values are from 0 to 7. The default level is 6 (informational).
<b>log</b>	The <b>log</b> option specifies logging action for the ACE. If you do not specify the <b>log</b> keyword or you specify the <b>log default</b> keyword, then message 106023 is generated when a packet is denied by the ACE. If you specify the <b>log</b> keyword alone or with a level or interval, then message 106100 is generated when a packet is denied by the ACE. Packets that are denied by the implicit deny at the end of an access list are not logged. You must implicitly deny packets with an ACE to enable logging.

# Configuring IPv6 Access Lists

This section includes the following topics:

- [Task Flow for Configuring IPv6 Access Lists, page 17-4](#)
- [Adding IPv6 Access Lists, page 17-5](#)
- [Adding Remarks to Access Lists, page 17-6](#)

## Task Flow for Configuring IPv6 Access Lists

Use the following guidelines to create and implement an access list:

- Create an access list by adding an ACE and applying an access list name, as shown in the [“Adding IPv6 Access Lists” section on page 17-5](#).
- Apply the access list to an interface. (See the [“Configuring Access Rules” section on page 32-7](#) for more information.)

## Adding IPv6 Access Lists

You can add a regular IPv6 access list or add an IPv6 access list with TCP.

To add a regular IPv6 access list, enter the following command:

Command	Purpose
<pre> <b>ipv6 access-list</b> <i>id</i> [<b>line</b> <i>line-num</i>] {<b>deny</b>   <b>permit</b>} {<i>protocol</i>   <b>object-group</b> <i>protocol_obj_grp_id</i>} {<i>source-ipv6-prefix/prefix-length</i>   <b>any</b>   <b>host</b> <i>source-ipv6-address</i>   <b>object-group</b> <i>network_obj_grp_id</i>} [<i>operator</i> {<i>port</i> [<i>port</i>]   <b>object-group</b> <i>service_obj_grp_id</i>}] {<i>destination-ipv6-prefix/prefix-length</i>   <b>any</b>   <b>host</b> <i>destination-ipv6-address</i>   <b>object-group</b> <i>network_obj_grp_id</i>} [<i>{operator port [port]   object-group</i> <i>service_obj_grp_id</i>}] [<b>log</b> [<i>level</i>] [<i>interval secs</i>]   <b>disable</b>   <b>default</b>]] </pre>	<p>Configures an IPv6 access list.</p> <p>The <b>any</b> keyword is an abbreviation for the IPv6 prefix <code>::/0</code>, indicating any IPv6 address.</p> <p>The <b>deny</b> keyword denies access if the conditions are matched.</p> <p>The <i>destination-ipv6-address</i> argument identifies the IPv6 address of the host receiving the traffic.</p> <p>The <i>destination-ipv6-prefix</i> argument identifies the IPv6 network address where the traffic is destined.</p> <p>The <b>disable</b> option disables syslog messaging.</p> <p>The <b>host</b> keyword indicates that the address refers to a specific host.</p> <p>The <i>id</i> keyword specifies the number of an access list.</p> <p>The <b>line</b> <i>line-num</i> option specifies the line number for inserting the access rule into the list. By default, the ACE is added to the end of the access list.</p> <p>The <i>network_obj_grp_id</i> argument specifies existing network object group identification.</p> <p>The <b>object-group</b> option specifies an object group.</p> <p>The <i>operator</i> option compares the source IP address or destination IP address ports. For a list of permitted operands, see the <a href="#">“Guidelines and Limitations”</a> section on page 17-2.</p> <p>The <b>permit</b> keyword permits access if the conditions are matched.</p> <p>The <i>port</i> option specifies the port that you permit or deny access. You can specify the port either by a number in the range of 0 to 65535 or by a literal name if the protocol is <b>tcp</b> or <b>udp</b>. For a list of permitted TCP or UDP literal names, see the <a href="#">“Guidelines and Limitations”</a> section on page 17-2.</p> <p>The <i>prefix-length</i> argument indicates how many of the high-order, contiguous bits of the address comprise the IPv6 prefix.</p> <p>The <i>protocol</i> argument specifies the name or number of an IP protocol.</p> <p>The <i>protocol_obj_grp_id</i> indicates the existing protocol object group ID.</p> <p>The <i>service_obj_grp_id</i> option specifies the object group.</p> <p>The <i>source-ipv6-address</i> specifies the address of the host sending traffic.</p> <p>The <i>source-ipv6-prefix</i> specifies the IPv6 address of traffic origin.</p>

### Example:

```

hostname(config)# ipv6 access-list acl_grp
permit tcp any host
3001:1::203:A0FF:FED6:162D

```

To configure an IPv6 access list with ICMP, enter the following command:

Command	Purpose
<b>ipv6 access-list</b> <i>id</i> [ <b>line</b> <i>line-num</i> ] { <b>deny</b>   <b>permit</b> } <b>icmp6</b> { <i>source-ipv6-prefix/prefix-length</i>   <b>any</b>   <b>host</b> <i>source-ipv6-address</i>   <b>object-group</b> <i>network_obj_grp_id</i> } { <i>destination-ipv6-prefix/prefix-length</i>   <b>any</b>   <b>host</b> <i>destination-ipv6-address</i>   <b>object-group</b> <i>network_obj_grp_id</i> } [ <i>icmp_type</i>   <b>object-group</b> <i>icmp_type_obj_grp_id</i> ] [ <b>log</b> [[ <i>level</i> ]]] [ <b>interval</b> <i>secs</i> ]   <b>disable</b>   <b>default</b> ]]	<p>Configures an IPv6 access list with ICMP.</p> <p>The <b>icmp6</b> keyword specifies that the access rule applies to ICMPv6 traffic passing through the adaptive security appliance.</p> <p>The <i>icmp_type</i> argument specifies the ICMP message type being filtered by the access rule. The value can be a valid ICMP type number from 0 to 255. (For a list of the permitted ICMP type literals, see the <a href="#">“Guidelines and Limitations”</a> section on page 17-2.)</p> <p>The <i>icmp_type_obj_grp_id</i> option specifies the object group ICMP type ID.</p> <p>For details about additional <b>ipv6 access-list</b> command parameters, see the preceding procedure for adding a regular IPv6 access list, or see the <b>ipv6 access-list</b> command in the <i>Cisco Security Appliance Command Reference</i>.</p>

**Example:**

```
hostname(config)# ipv6 access list acl_grp
permit tcp any host
3001:1::203:A0FF:FED6:162D
```

## Adding Remarks to Access Lists

You can include remarks about entries in any access list, including extended, EtherType, IPv6, standard, and Webtype access lists. The remarks make the access list easier to understand.

To add a remark after the last **access-list** command you entered, enter the following command:

Command	Purpose
<b>access-list</b> <i>access_list_name</i> <b>remark</b> <i>text</i>	<p>Adds a remark after the last access-list command you entered.</p> <p>The text can be up to 100 characters in length. You can enter leading spaces at the beginning of the text. Trailing spaces are ignored.</p> <p>If you enter the remark before any <b>access-list</b> command, then the remark is the first line in the access list.</p> <p>If you delete an access list using the <b>no access-list</b> <i>access_list_name</i> command, then all the remarks are also removed.</p>

**Example**

You can add remarks before each ACE, and the remarks appear in the access list in these locations. Entering a dash (-) at the beginning of a remark helps set it apart from an ACE.

```
hostname(config)# access-list OUT remark - this is the inside admin address
hostname(config)# access-list OUT extended permit ip host 209.168.200.3 any
hostname(config)# access-list OUT remark - this is the hr admin address
hostname(config)# access-list OUT extended permit ip host 209.168.200.4 any
```

# Monitoring IPv6 Access Lists

To monitor IPv6 access lists, perform one of the following tasks:

Command	Purpose
<code>show ipv6 access-list</code>	Displays all IPv6 access list information.

## Configuration Examples for IPv6 Access Lists

The following example shows how to configure IPv6 access lists:

The following example allows any host using TCP to access the 3001:1::203:A0FF:FED6:162D server:

```
hostname(config)# ipv6 access-list acl_grp permit tcp any host 3001:1::203:A0FF:FED6:162D
```

The following example uses **eq** and a port to deny access to just FTP:

```
hostname(config)# ipv6 access-list acl_out deny tcp any host 3001:1::203:A0FF:FED6:162D eq ftp
hostname(config)# access-group acl_out in interface inside
```

The following example uses **lt** to permit access to all ports less than port 2025, which permits access to the well-known ports (1 to 1024):

```
hostname(config)# ipv6 access-list acl_dmz1 permit tcp any host 3001:1::203:A0FF:FED6:162D lt 1025
hostname(config)# access-group acl_dmz1 in interface dmz1
```

## Where to Go Next

Apply the access list to an interface. (See the [“Configuring Access Rules”](#) section on page 32-7 for more information.)

## Feature History for IPv6 Access Lists

Table 17-2 lists the release history for this feature.

**Table 17-2** Feature History for IPv6 Access Lists

Feature Name	Releases	Feature Information
IPv6 access lists	7.0(1)	The following command was introduced: <b>ipv6 access-list</b> .

# CHAPTER 18

## Configuring Logging for Access Lists

---

This chapter describes how to configure access list logging for extended access lists and Webtype access lists, and it describes how to manage deny flows.

This chapter includes the following sections:

- [Configuring Logging for Access Lists, page 18-1](#)
- [Managing Deny Flows, page 18-5](#)

## Configuring Logging for Access Lists

This section includes the following topics:

- [Information About Logging Access List Activity, page 18-1](#)
- [Licensing Requirements for Access List Logging, page 18-2](#)
- [Guidelines and Limitations, page 18-2](#)
- [Default Settings, page 18-3](#)
- [Configuring Access List Logging, page 18-3](#)
- [Monitoring Access Lists, page 18-4](#)
- [Configuration Examples for Access List Logging, page 18-4](#)
- [Feature History for Access List Logging, page 18-5](#)

## Information About Logging Access List Activity

By default, when traffic is denied by an extended ACE or a Webtype ACE, the adaptive security appliance generates system message 106023 for each denied packet in the following form:

```
%ASA|PIX-4-106023: Deny protocol src [interface_name:source_address/source_port] dst  
interface_name:dest_address/dest_port [type {string}, code {code}] by access_group acl_id
```

If the adaptive security appliance is attacked, the number of system messages for denied packets can be very large. We recommend that you instead enable logging using system message 106100, which provides statistics for each ACE and enables you to limit the number of system messages produced. Alternatively, you can disable all logging.

**Note**

Only ACEs in the access list generate logging messages; the implicit deny at the end of the access list does not generate a message. If you want all denied traffic to generate messages, add the implicit ACE manually to the end of the access list, as shown in the following example:

```
hostname(config)# access-list TEST deny ip any any log
```

The **log** options at the end of the extended **access-list** command enable you to set the following behavior:

- Enable message 106100 instead of message 106023
- Disable all logging
- Return to the default logging using message 106023

System message 106100 uses the following form:

```
%ASA|PIX-n-106100: access-list acl_id {permitted | denied} protocol
interface_name/source_address(source_port) -> interface_name/dest_address(dest_port)
hit-cnt number ({first hit | number-second interval})
```

When you enable logging for message 106100, if a packet matches an ACE, the adaptive security appliance creates a flow entry to track the number of packets received within a specific interval. The adaptive security appliance generates a system message at the first hit and at the end of each interval, identifying the total number of hits during the interval and the timestamp for the last hit. At the end of each interval, the adaptive security appliance resets the hit count to 0. If no packets match the ACE during an interval, the adaptive security appliance deletes the flow entry.

A flow is defined by the source and destination IP addresses, protocols, and ports. Because the source port might differ for a new connection between the same two hosts, you might not see the same flow increment because a new flow was created for the connection. See the [“Managing Deny Flows” section on page 18-5](#) to limit the number of logging flows.

Permitted packets that belong to established connections do not need to be checked against access lists; only the initial packet is logged and included in the hit count. For connectionless protocols, such as ICMP, all packets are logged, even if they are permitted, and all denied packets are logged.

See the *Cisco ASA 5500 Series System Log Messages* for detailed information about this system message.

## Licensing Requirements for Access List Logging

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

**Firewall Mode Guidelines**

Supported only in routed and transparent firewall modes.

**IPv6 Guidelines**

Supports IPv6.

**Additional Guidelines and Limitations**

ACE logging generates system log message 106023 for denied packets. A deny ACE must be present to log denied packets.

## Default Settings

Table 18-1 lists the default settings for extended access list parameters.

**Table 18-1**      *Default Extended Access List Parameters*

Parameters	Default
log	When the <b>log</b> keyword is specified, the default level for system log message 106100 is 6 (informational), and the default interval is 300 seconds.

## Configuring Access List Logging

This sections describes how to configure access list logging.

**Note**

For complete access list command syntax, see the [“Configuring Extended Access Lists”](#) section on page 13-3 and the [“Using Webtype Access Lists”](#) section on page 16-2.

To configure logging for an ACE, enter the following command:

Command	Purpose
<b>access-list</b> <i>access_list_name</i> [ <b>extended</b> ] { <b>deny</b> / <b>permit</b> }... <b>[log</b> [[ <i>level</i> ] [ <i>interval secs</i> ]   <b>disable</b>   <b>default</b> ]]	<p>Configures logging for an ACE.</p> <p>The <b>access-list</b> <i>access_list_name</i> syntax specifies the access list for which you want to configure logging.</p> <p>The <b>extended</b> option adds an ACE.</p> <p>The <b>deny</b> keyword denies a packet if the conditions are matched. Some features do not allow deny ACEs, such as NAT. (See the command documentation for each feature that uses an access list for more information.)</p> <p>The <b>permit</b> keyword permits a packet if the conditions are matched.</p> <p>If you enter the <b>log</b> option without any arguments, you enable system log message 106100 at the default level (6) and for the default interval (300 seconds). See the following options:</p> <ul style="list-style-type: none"> <li><i>level</i>—A severity level between 0 and 7. The default is 6.</li> <li><b>interval secs</b>—The time interval in seconds between system messages, from 1 to 600. The default is 300. This value is also used as the timeout value for deleting an inactive flow.</li> <li><b>disable</b>—Disables all access list logging.</li> <li><b>default</b>—Enables logging to message 106023. This setting is the same as having no <b>log</b> option.</li> </ul> <p>(See the <b>access-list</b> command in the <i>Cisco Security Appliance Command Reference</i> for more information about command options.)</p>

## Monitoring Access Lists

To monitor access lists, enter one of the following commands:

Command	Purpose
<b>show access list</b>	Displays the access list entries by number.
<b>show running-config access-list</b>	Displays the current running access-list configuration.

## Configuration Examples for Access List Logging

This section includes sample configurations for logging access lists.

You might configure the following access list:

```
hostname(config)# access-list outside-acl permit ip host 1.1.1.1 any log 7 interval 600
hostname(config)# access-list outside-acl permit ip host 2.2.2.2 any
hostname(config)# access-list outside-acl deny ip any any log 2
hostname(config)# access-group outside-acl in interface outside
```

When the first ACE of outside-acl permits a packet, the adaptive security appliance generates the following system message:

```
%ASA|PIX-7-106100: access-list outside-acl permitted tcp outside/1.1.1.1(12345) ->
inside/192.168.1.1(1357) hit-cnt 1 (first hit)
```

Although 20 additional packets for this connection arrive on the outside interface, the traffic does not have to be checked against the access list, and the hit count does not increase.

If one or more connections by the same host are initiated within the specified 10 minute interval (and the source and destination ports remain the same), then the hit count is incremented by 1, and the following message displays at the end of the 10 minute interval:

```
%ASA|PIX-7-106100: access-list outside-acl permitted tcp outside/1.1.1.1(12345)->
inside/192.168.1.1(1357) hit-cnt 2 (600-second interval)
```

When the third ACE denies a packet, the adaptive security appliance generates the following system message:

```
%ASA|PIX-2-106100: access-list outside-acl denied ip outside/3.3.3.3(12345) ->
inside/192.168.1.1(1357) hit-cnt 1 (first hit)
```

If 20 additional attempts occur within a 5 minute interval (the default), the following message appears at the end of 5 minutes:

```
%ASA|PIX-2-106100: access-list outside-acl denied ip outside/3.3.3.3(12345) ->
inside/192.168.1.1(1357) hit-cnt 21 (300-second interval)
```

## Feature History for Access List Logging

Table 18-2 lists the release history for this feature.

**Table 18-2** Feature History for Access List Logging

Feature Name	Releases	Feature Information
Access list logging	7.0	You can enable logging using system message 106100, which provides statistics for each ACE and lets you limit the number of system messages produced.  The following command was introduced: <b>access-list</b> .
ACL Timestamp	8.3(1)	The adaptive security appliance reports the timestamp for the last access rule hit.

## Managing Deny Flows

This section includes the following topics:

- [Information About Managing Deny Flows, page 18-6](#)
- [Licensing Requirements for Managing Deny Flows, page 18-6](#)
- [Guidelines and Limitations, page 18-6](#)
- [Managing Deny Flows, page 18-7](#)
- [Monitoring Deny Flows, page 18-8](#)

- [Feature History for Managing Deny Flows, page 18-8](#)

## Information About Managing Deny Flows

When you enable logging for message 106100, if a packet matches an ACE, the adaptive security appliance creates a flow entry to track the number of packets received within a specific interval. The adaptive security appliance has a maximum of 32 K logging flows for ACEs. A large number of flows can exist concurrently at any point of time. To prevent unlimited consumption of memory and CPU resources, the adaptive security appliance places a limit on the number of concurrent *deny* flows; the limit is placed on deny flows only (not on permit flows) because they can indicate an attack. When the limit is reached, the adaptive security appliance does not create a new deny flow for logging until the existing flows expire.

For example, if someone initiates a DoS attack, the adaptive security appliance can create a large number of deny flows in a short period of time. Restricting the number of deny flows prevents unlimited consumption of memory and CPU resources.

When you reach the maximum number of deny flows, the adaptive security appliance issues system message 106100:

```
%ASA|PIX-1-106101: The number of ACL log deny-flows has reached limit (number).
```

The **access-list alert-interval** command sets the time interval for generating the system log message 106001. The system log message 106001 alerts you that the adaptive security appliance has reached a deny flow maximum. When the deny flow maximum is reached, another system log message 106001 is generated if at least six seconds have passed since the last 106001 message was generated.

## Licensing Requirements for Managing Deny Flows

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported only in routed and transparent firewall modes.

### IPv6 Guidelines

Supports IPv6.

### Additional Guidelines and Limitations

The adaptive security appliance places a limit on the number of concurrent *deny* flows only—not permit flows.

## Default Settings

Table 18-1 lists the default settings for managing deny flows.

**Table 18-3** Default Parameters for Managing Deny Flows

Parameters	Default
<i>numbers</i>	The <i>numbers</i> argument specifies the maximum number of deny flows. The default is 4096.
<i>secs</i>	The <i>secs</i> argument specifies the time, in seconds, between system messages. The default is 300.

## Managing Deny Flows

To configure the maximum number of deny flows and to set the interval between deny flow alert messages (106100), enter the following command:

Command	Purpose
<b>access-list deny-flow-max</b> <i>number</i>	Sets the maximum number of deny flows.
<b>Example:</b> hostname(config)# access-list deny-flow-max 3000	The <i>numbers</i> argument specifies the maximum number, which can be between 1 and 4096. The default is 4096.

To set the amount of time between system messages (number 106101), which identifies that the maximum number of deny flows was reached, enter the following command:

Command	Purpose
<b>access-list alert-interval</b> <i>secs</i>	Sets the time, in seconds, between system messages.
<b>Example:</b> hostname(config)# access-list alert-interval 200	The <i>secs</i> argument specifies the time interval between each deny flow maximum message. Valid values are from 1 to 3600 seconds. The default is 300 seconds.

# Monitoring Deny Flows

To monitor access lists, enter one of the following commands:

Command	Purpose
<code>show access-list</code>	Displays access list entries by number.
<code>show running-config access-list</code>	Displays the current running access-list configuration.

# Feature History for Managing Deny Flows

Table 18-2 lists the release history for this feature.

Table 18-4 Feature History for Managing Deny Flows

Feature Name	Releases	Feature Information
Managing Deny Flows	7.0	<p>You can configure the maximum number of deny flows and set the interval between deny flow alert messages.</p> <p>The following commands were introduced: <b>access-list deny-flow</b> and <b>access-list alert-interval</b>.</p>

## **PART 4**

### **Configuring IP Routing**

# CHAPTER 19

## Information About Routing

---

This chapter describes underlying concepts of how routing behaves within the adaptive security appliance, and the routing protocols that are supported.

The chapter includes the following sections:

- [Information About Routing, page 19-1](#)
- [How Routing Behaves Within the Adaptive Security Appliance, page 19-4](#)
- [Supported Internet Protocols for Routing, page 19-5](#)
- [Information About the Routing Table, page 19-5](#)
- [Information About IPv6 Support, page 19-9](#)
- [Disabling Proxy ARPs, page 19-11](#)

## Information About Routing

Routing is the act of moving information across an internetwork from a source to a destination. Along the way, at least one intermediate node typically is encountered. Routing involves two basic activities: determining optimal routing paths and transporting information groups (typically called packets) through an internetwork. In the context of the routing process, the latter of these is referred to as packet switching. Although packet switching is relatively straightforward, path determination can be very complex.

## Switching

Switching algorithms is relatively simple; it is the same for most routing protocols. In most cases, a host determines that it must send a packet to another host. Having acquired a router's address by some means, the source host sends a packet addressed specifically to a router's physical (Media Access Control [MAC]-layer) address, this time with the protocol (network layer) address of the destination host.

As it examines the packet's destination protocol address, the router determines that it either knows or does not know how to forward the packet to the next hop. If the router does not know how to forward the packet, it typically drops the packet. If the router knows how to forward the packet, however, it changes the destination physical address to that of the next hop and transmits the packet.

The next hop may be the ultimate destination host. If not, the next hop is usually another router, which executes the same switching decision process. As the packet moves through the internetwork, its physical address changes, but its protocol address remains constant.

## Path Determination

Routing protocols use metrics to evaluate what path will be the best for a packet to travel. A metric is a standard of measurement, such as path bandwidth, that is used by routing algorithms to determine the optimal path to a destination. To aid the process of path determination, routing algorithms initialize and maintain routing tables, which contain route information. Route information varies depending on the routing algorithm used.

Routing algorithms fill routing tables with a variety of information. Destination/next hop associations tell a router that a particular destination can be reached optimally by sending the packet to a particular router representing the “next hop” on the way to the final destination. When a router receives an incoming packet, it checks the destination address and attempts to associate this address with a next hop.

Routing tables also can contain other information, such as data about the desirability of a path. Routers compare metrics to determine optimal routes, and these metrics differ depending on the design of the routing algorithm used.

Routers communicate with one another and maintain their routing tables through the transmission of a variety of messages. The routing update message is one such message that generally consists of all or a portion of a routing table. By analyzing routing updates from all other routers, a router can build a detailed picture of network topology. A link-state advertisement, another example of a message sent between routers, informs other routers of the state of the sender's links. Link information also can be used to build a complete picture of network topology to enable routers to determine optimal routes to network destinations.

**Note**

---

Asymmetric routing is not supported on the adaptive security appliance.

---

## Supported Route Types

There are several types of route types that a router can use. The adaptive security appliance uses the following route types:

- [Static Versus Dynamic, page 19-2](#)
- [Single-Path Versus Multipath, page 19-3](#)
- [Flat Versus Hierarchical, page 19-3](#)
- [Link-State Versus Distance Vector, page 19-3](#)

### Static Versus Dynamic

Static routing algorithms are hardly algorithms at all, but are table mappings established by the network administrator before the beginning of routing. These mappings do not change unless the network administrator alters them. Algorithms that use static routes are simple to design and work well in environments where network traffic is relatively predictable and where network design is relatively simple.

Because static routing systems cannot react to network changes, they generally are considered unsuitable for today's large, constantly changing networks. Most of the dominant routing algorithms today are dynamic routing algorithms, which adjust to changing network circumstances by analyzing incoming routing update messages. If the message indicates that a network change has occurred, the routing software recalculates routes and sends out new routing update messages. These messages permeate the network, stimulating routers to rerun their algorithms and change their routing tables accordingly.

Dynamic routing algorithms can be supplemented with static routes where appropriate. A router of last resort (a router to which all unroutable packets are sent), for example, can be designated to act as a repository for all unroutable packets, ensuring that all messages are at least handled in some way.

**Note**

There is no dynamic routing support in multi-context mode. Because of this, there is no route tracking.

## Single-Path Versus Multipath

Some sophisticated routing protocols support multiple paths to the same destination. Unlike single-path algorithms, these multipath algorithms permit traffic multiplexing over multiple lines. The advantages of multipath algorithms are obvious: They can provide substantially better throughput and reliability. This is generally called load sharing.

## Flat Versus Hierarchical

Some routing algorithms operate in a flat space, while others use routing hierarchies. In a flat routing system, the routers are peers of all others. In a hierarchical routing system, some routers form what amounts to a routing backbone. Packets from nonbackbone routers travel to the backbone routers, where they are sent through the backbone until they reach the general area of the destination. At this point, they travel from the last backbone router through one or more nonbackbone routers to the final destination.

Routing systems often designate logical groups of nodes, called domains, autonomous systems, or areas. In hierarchical systems, some routers in a domain can communicate with routers in other domains, while others can communicate only with routers within their domain. In very large networks, additional hierarchical levels may exist, with routers at the highest hierarchical level forming the routing backbone.

The primary advantage of hierarchical routing is that it mimics the organization of most companies and therefore supports their traffic patterns well. Most network communication occurs within small company groups (domains). Because intradomain routers need to know only about other routers within their domain, their routing algorithms can be simplified, and, depending on the routing algorithm being used, routing update traffic can be reduced accordingly.

## Link-State Versus Distance Vector

Link-state algorithms (also known as shortest path first algorithms) flood routing information to all nodes in the internetwork. Each router, however, sends only the portion of the routing table that describes the state of its own links. In link-state algorithms, each router builds a picture of the entire network in its routing tables. Distance vector algorithms (also known as Bellman-Ford algorithms) call for each router to send all or some portion of its routing table, but only to its neighbors. In essence, link-state

algorithms send small updates everywhere, while distance vector algorithms send larger updates only to neighboring routers. Distance vector algorithms know only about their neighbors. Typically, this type of algorithm is used in conjunction with OSPF routing protocols.

## How Routing Behaves Within the Adaptive Security Appliance

The adaptive security appliance uses both routing table and XLATE tables for routing decisions. To handle destination IP translated traffic, that is, untranslated traffic, the adaptive security appliance searches for existing XLATE, or static translation to select the egress interface.

### Egress Interface Selection Process

The selection process is as follows:

1. If destination IP translating XLATE already exists, the egress interface for the packet is determined from the XLATE table, but not from the routing table.
2. If destination IP translating XLATE does not exist, but a matching static translation exists, then the egress interface is determined from the static route and an XLATE is created, and the routing table is not used.
3. If destination IP translating XLATE does not exist and no matching static translation exists, the packet is not destination IP translated. The adaptive security appliance processes this packet by looking up the route to select egress interface, then source IP translation is performed (if necessary).

For regular dynamic outbound NAT, initial outgoing packets are routed using the route table and then creating the XLATE. Incoming return packets are forwarded using existing XLATE only. For static NAT, destination translated incoming packets are always forwarded using existing XLATE or static translation rules.

### Next Hop Selection Process

After selecting egress interface using any method described above, an additional route lookup is performed to find out suitable next hop(s) that belong to previously selected egress interface. If there are no routes in routing table that explicitly belong to selected interface, the packet is dropped with the level 6 error message 110001 (no route to host), even if there is another route for a given destination network that belongs to different egress interface. If the route that belongs to selected egress interface is found, the packet is forwarded to corresponding next hop.

Load sharing on the adaptive security appliance is possible only for multiple next-hops available using single egress interface. Load sharing cannot share multiple egress interfaces.

If dynamic routing is in use on adaptive security appliance and route table changes after XLATE creation, for example route flap, then destination translated traffic is still forwarded using old XLATE, not via route table, until XLATE times out. It may be either forwarded to wrong interface or dropped with message 110001 (no route to host), if old route was removed from the old interface and attached to another one by routing process.

The same problem may happen when there is no route flaps on the adaptive security appliance itself, but some routing process is flapping around it, sending source translated packets that belong to the same flow through the adaptive security appliance using different interfaces. Destination translated return packets may be forwarded back using the wrong egress interface.

This issue has a high probability in same security traffic configuration, where virtually any traffic may be either source-translated or destination-translated, depending on direction of initial packet in the flow. When this issue occurs after a route flap, it can be resolved manually by using the **clear xlate** command, or automatically resolved by an XLATE timeout. XLATE timeout may be decreased if necessary. To ensure that this rarely happens, make sure that there is no route flaps on adaptive security appliance and around it. That is, ensure that destination translated packets that belong to the same flow are always forwarded the same way through the adaptive security appliance.

## Supported Internet Protocols for Routing

The adaptive security appliance supports several internet protocols for routing. Each protocol is briefly described in this section.

- Enhanced Interior Gateway Routing Protocol (EIGRP)

EIGRP provides compatibility and seamless interoperability with IGRP routers. An automatic-redistribution mechanism allows IGRP routes to be imported into Enhanced IGRP, and vice versa, so it is possible to add Enhanced IGRP gradually into an existing IGRP network.

For more information about configuring EIGRP, see the [“Configuring EIGRP” section on page 24-3](#).

- Open Shortest Path First (OSPF)

Open Shortest Path First (OSPF) is a routing protocol developed for Internet Protocol (IP) networks by the interior gateway protocol (IGP) working group of the Internet Engineering Task Force (IETF). OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area includes an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

For more information about configuring OSPF, see the [“Configuring OSPF” section on page 22-3](#).

- Routing Information Protocol

The Routing Information Protocol (RIP) is a distance-vector protocol that uses hop count as its metric. RIP is widely used for routing traffic in the global Internet and is an interior gateway protocol (IGP), which means that it performs routing within a single autonomous system.

For more information about configuring RIP, see the [“Configuring RIP” section on page 23-3](#).

## Information About the Routing Table

This section includes the following topics:

- [Displaying the Routing Table, page 19-5](#)
- [How the Routing Table Is Populated, page 19-6](#)
- [How Forwarding Decisions are Made, page 19-8](#)

## Displaying the Routing Table

To view the entries in the routing table, enter the following command:

```
hostname# show route
```

Codes: C - connected, S - static, I - IGRP, R - RIP, M - mobile, B - BGP  
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area

```

N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default, U - per-user static route, o - ODR
P - periodic downloaded static route

```

Gateway of last resort is 10.86.194.1 to network 0.0.0.0

```

S    10.1.1.0 255.255.255.0 [3/0] via 10.86.194.1, outside
C    10.86.194.0 255.255.254.0 is directly connected, outside
S*   0.0.0.0 0.0.0.0 [1/0] via 10.86.194.1, outside

```

On the ASA 5505 adaptive security appliance, the following route is also shown. It is the internal loopback interface, which is used by the VPN hardware client feature for individual user authentication.

```

C 127.1.0.0 255.255.0.0 is directly connected, _internal_loopback

```

## How the Routing Table Is Populated

The adaptive security appliance routing table can be populated by statically defined routes, directly connected routes, and routes discovered by the RIP, EIGRP, and OSPF routing protocols. Because the adaptive security appliance can run multiple routing protocols in addition to having static and connected routes in the routing table, it is possible that the same route is discovered or entered in more than one manner. When two routes to the same destination are put into the routing table, the one that remains in the routing table is determined as follows:

- If the two routes have different network prefix lengths (network masks), then both routes are considered unique and are entered in to the routing table. The packet forwarding logic then determines which of the two to use.

For example, if the RIP and OSPF processes discovered the following routes:

- RIP: 192.168.32.0/24
- OSPF: 192.168.32.0/19

Even though OSPF routes have the better administrative distance, both routes are installed in the routing table because each of these routes has a different prefix length (subnet mask). They are considered different destinations and the packet forwarding logic determine which route to use.

- If the adaptive security appliance learns about multiple paths to the same destination from a single routing protocol, such as RIP, the route with the better metric (as determined by the routing protocol) is entered into the routing table.

Metrics are values associated with specific routes, ranking them from most preferred to least preferred. The parameters used to determine the metrics differ for different routing protocols. The path with the lowest metric is selected as the optimal path and installed in the routing table. If there are multiple paths to the same destination with equal metrics, load balancing is done on these equal cost paths.

- If the adaptive security appliance learns about a destination from more than one routing protocol, the administrative distances of the routes are compared and the routes with lower administrative distance are entered into the routing table.

You can change the administrative distances for routes discovered by or redistributed into a routing protocol. If two routes from two different routing protocols have the same administrative distance, then the route with the lower *default* administrative distance is entered into the routing table. In the case of EIGRP and OSPF routes, if the EIGRP route and the OSPF route have the same administrative distance, then the EIGRP route is chosen by default.

Administrative distance is a route parameter that the adaptive security appliance uses to select the best path when there are two or more different routes to the same destination from two different routing protocols. Because the routing protocols have metrics based on algorithms that are different from the other protocols, it is not always possible to determine the “best path” for two routes to the same destination that were generated by different routing protocols.

Each routing protocol is prioritized using an administrative distance value. [Table 19-1](#) shows the default administrative distance values for the routing protocols supported by the adaptive security appliance.

**Table 19-1**      *Default Administrative Distance for Supported Routing Protocols*

Route Source	Default Administrative Distance
Connected interface	0
Static route	1
EIGRP Summary Route	5
Internal EIGRP	90
OSPF	110
RIP	120
EIGRP external route	170
Unknown	255

The smaller the administrative distance value, the more preference is given to the protocol. For example, if the adaptive security appliance receives a route to a certain network from both an OSPF routing process (default administrative distance - 110) and a RIP routing process (default administrative distance - 120), the adaptive security appliance chooses the OSPF route because OSPF has a higher preference. This means the router adds the OSPF version of the route to the routing table.

In this example, if the source of the OSPF-derived route was lost (for example, due to a power shutdown), the adaptive security appliance would then use the RIP-derived route until the OSPF-derived route reappears.

The administrative distance is a local setting. For example, if you use the **distance-ospf** command to change the administrative distance of routes obtained through OSPF, that change would only affect the routing table for the adaptive security appliance the command was entered on. The administrative distance is not advertised in routing updates.

Administrative distance does not affect the routing process. The OSPF and RIP routing processes only advertise the routes that have been discovered by the routing process or redistributed into the routing process. For example, the RIP routing process advertises RIP routes, even if routes discovered by the OSPF routing process are used in the adaptive security appliance routing table.

## Backup Routes

A backup route is registered when the initial attempt to install the route in the routing table fails because another route was installed instead. If the route that was installed in the routing table fails, the routing table maintenance process calls each routing protocol process that has registered a backup route and requests them to reinstall the route in the routing table. If there are multiple protocols with registered backup routes for the failed route, the preferred route is chosen based on administrative distance.

Because of this process, you can create “floating” static routes that are installed in the routing table when the route discovered by a dynamic routing protocol fails. A floating static route is simply a static route configured with a greater administrative distance than the dynamic routing protocols running on the adaptive security appliance. When the corresponding route discovered by a dynamic routing process fails, the static route is installed in the routing table.

## How Forwarding Decisions are Made

Forwarding decisions are made as follows:

- If the destination does not match an entry in the routing table, the packet is forwarded through the interface specified for the default route. If a default route has not been configured, the packet is discarded.
- If the destination matches a single entry in the routing table, the packet is forwarded through the interface associated with that route.
- If the destination matches more than one entry in the routing table, and the entries all have the same network prefix length, the packets for that destination are distributed among the interfaces associated with that route.
- If the destination matches more than one entry in the routing table, and the entries have different network prefix lengths, then the packet is forwarded out of the interface associated with the route that has the longer network prefix length.

For example, a packet destined for 192.168.32.1 arrives on an interface of an adaptive security appliance with the following routes in the routing table:

```
hostname# show route
....
R   192.168.32.0/24 [120/4] via 10.1.1.2
O   192.168.32.0/19 [110/229840] via 10.1.1.3
....
```

In this case, a packet destined to 192.168.32.1 is directed toward 10.1.1.2, because 192.168.32.1 falls within the 192.168.32.0/24 network. It also falls within the other route in the routing table, but the 192.168.32.0/24 has the longest prefix within the routing table (24 bits versus 19 bits). Longer prefixes are always preferred over shorter ones when forwarding a packet.

## Dynamic Routing and Failover

Because static routing systems cannot react to network changes, they generally are considered unsuitable for today's large, constantly changing networks. Most of the dominant routing algorithms today are dynamic routing algorithms, which adjust to changing network circumstances by analyzing incoming

routing update messages. If the message indicates that a network change has occurred, the routing software recalculates routes and sends out new routing update messages. These messages permeate the network, stimulating routers to rerun their algorithms and change their routing tables accordingly.

Dynamic routing algorithms can be supplemented with static routes where appropriate. A router of last resort (a router to which all unroutable packets are sent), for example, can be designated to act as a repository for all unroutable packets, ensuring that all messages are at least handled in some way.

Dynamic routes are not replicated to the standby unit or failover group in a failover configuration. Therefore, immediately after a failover occurs, some packets received by the adaptive security appliance may be dropped because of a lack of routing information or routed to a default static route while the routing table is repopulated by the configured dynamic routing protocols.

For more information about static routes and how to configure them, see the [“Configuring Static and Default Routes” section on page 20-1](#).

## Information About IPv6 Support

Many, but not all, features on the adaptive security appliance supports IPv6 traffic. This section describes the commands and features that support IPv6, and includes the following topics:

- [Features that Support IPv6, page 19-9](#)
- [IPv6-Enabled Commands, page 19-10](#)
- [Entering IPv6 Addresses in Commands, page 19-11](#)

## Features that Support IPv6

The following features support IPv6:

### Note

For features that use the Modular Policy Framework, be sure to use the **match any** command to match IPv6 traffic; other **match** commands do not support IPv6.

- The following application inspections support IPv6 traffic:
  - FTP
  - HTTP
  - ICMP
  - SIP
  - SMTP
  - IPSec-pass-thru
- IPS
- NetFlow Secure Event Logging filtering
- Connection limits, timeouts, and TCP randomization
- TCP Normalization
- TCP state bypass
- Access group, using an IPv6 access list

- Static Routes
- VPN (all types)

## IPv6-Enabled Commands

The following adaptive security appliance commands can accept and display IPv6 addresses:

- **capture**
- **configure**
- **copy**
- **http**
- **name**
- **object-group**
- **ping**
- **show conn**
- **show local-host**
- **show tcpstat**
- **ssh**
- **telnet**
- **tftp-server**
- **who**
- **write**

The following commands were modified to work for IPv6:

- **debug**
- **fragment**
- **ip verify**
- **mtu**
- **icmp** (entered as **ipv6 icmp**)

## IPv6 Command Guidelines in Transparent Firewall Mode

The **ipv6 address** and **ipv6 enable** commands are available in global configuration mode instead of interface configuration mode. The **ipv6 address** command does not support the **eui** keyword. (The **ipv6 address link-local** command is still available in interface configuration mode.

The following IPv6 commands are not supported in transparent firewall mode, because they require router capabilities:

- **ipv6 address autoconfig**
- **ipv6 nd prefix**
- **ipv6 nd ra-interval**
- **ipv6 nd ra-lifetime**

- **ipv6 nd suppress-ra**

The **ipv6 local pool** VPN command is not supported, because transparent mode does not support VPN.

## Entering IPv6 Addresses in Commands

When entering IPv6 addresses in commands that support them, simply enter the IPv6 address using standard IPv6 notation, for example:

```
ping fe80::2e0:b6ff:fe01:3b7a.
```

The adaptive security appliance correctly recognizes and processes the IPv6 address. However, you must enclose the IPv6 address in square brackets ( [ ] ) in the following situations:

- You need to specify a port number with the address, for example:

```
[fe80::2e0:b6ff:fe01:3b7a]:8080.
```

- The command uses a colon as a separator, such as the **write net** command and **config net** command, for example:

```
configure net [fe80::2e0:b6ff:fe01:3b7a]:/tftp/config/asacnfig.
```

## Disabling Proxy ARPs

When a host sends IP traffic to another device on the same Ethernet network, the host needs to know the MAC address of the device. ARP is a Layer 2 protocol that resolves an IP address to a MAC address. A host sends an ARP request asking “Who is this IP address?” The device owning the IP address replies, “I own that IP address; here is my MAC address.”

Proxy ARP is used when a device responds to an ARP request with its own MAC address, even though the device does not own the IP address. The adaptive security appliance uses proxy ARP when you configure NAT and specify a mapped address that is on the same network as the adaptive security appliance interface. The only way traffic can reach the hosts is if the adaptive security appliance uses proxy ARP to claim that the adaptive security appliance MAC address is assigned to destination mapped addresses.

In rare circumstances, you might want to disable proxy ARP for NAT addresses.

If you have a VPN client address pool that overlaps with an existing network, the adaptive security appliance by default sends proxy ARPs on all interfaces. If you have another interface that is on the same Layer 2 domain, it will see the ARP requests and will answer with the MAC address of its interface. The result of this is that the return traffic of the VPN clients towards the internal hosts will go to the wrong interface and will get dropped. In this case, you need to disable proxy ARPs for the interface where you do not want proxy ARPs.

To disable proxy ARPs, enter the following command:

```
hostname(config)# sysopt noproxyarp interface
```

-

## CHAPTER 20

# Configuring Static and Default Routes

---

This chapter describes how to configure static and default routes on the adaptive security appliance and includes the following sections:

- [Information About Static and Default Routes, page 20-1](#)
- [Licensing Requirements for Static and Default Routes, page 20-2](#)
- [Guidelines and Limitations, page 20-2](#)
- [Configuring Static and Default Routes, page 20-2](#)
- [Monitoring a Static or Default Route, page 20-6](#)
- [Configuration Examples for Static or Default Routes, page 20-8](#)
- [Feature History for Static and Default Routes, page 20-9](#)

## Information About Static and Default Routes

To route traffic to a non-connected host or network, you must define a static route to the host or network or, at a minimum, a default route for any networks to which the adaptive security appliance is not directly connected; for example, when there is a router between a network and the adaptive security appliance.

Without a static or default route defined, traffic to non-connected hosts or networks generates the following syslog message:

```
%ASA-6-110001: No route to dest_address from source_address
```

Multiple context mode does not support dynamic routing.

You might want to use static routes in single context mode in the following cases:

- Your networks use a different router discovery protocol from EIGRP, RIP, or OSPF.
- Your network is small and you can easily manage static routes.
- You do not want the traffic or CPU overhead associated with routing protocols.

The simplest option is to configure a default route to send all traffic to an upstream router, relying on the router to route the traffic for you. However, in some cases the default gateway might not be able to reach the destination network, so you must also configure more specific static routes. For example, if the default gateway is outside, then the default route cannot direct traffic to any inside networks that are not directly connected to the adaptive security appliance.

In transparent firewall mode, for traffic that originates on the adaptive security appliance and is destined for a non-directly connected network, you need to configure either a default route or static routes so the adaptive security appliance knows out of which interface to send traffic. Traffic that originates on the

adaptive security appliance might include communications to a syslog server, Websense or N2H2 server, or AAA server. If you have servers that cannot all be reached through a single default route, then you must configure static routes. Additionally, the adaptive security appliance supports up to three equal cost routes on the same interface for load balancing.

## Licensing Requirements for Static and Default Routes

Model	License Requirement
All models	Base License.

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

### IPv6 Guidelines

Supports IPv6.

### Additional Guidelines

IPv6 static routes are not supported in transparent mode in ASDM.

## Configuring Static and Default Routes

This section explains how to configure a static, and a static default route and includes the following topics:

- [Configuring a Static Route, page 20-3](#)
- [Configuring a Default Static Route, page 20-4](#)
- [Configuring IPv6 Default and Static Routes, page 20-5](#)

## Configuring a Static Route

Static routing algorithms are basically table mappings established by the network administrator before the beginning of routing. These mappings do not change unless the network administrator alters them. Algorithms that use static routes are simple to design and work well in environments where network traffic is relatively predictable and where network design is relatively simple. Because of this fact, static routing systems cannot react to network changes.

Static routes remain in the routing table even if the specified gateway becomes unavailable. If the specified gateway becomes unavailable, you need to remove the static route from the routing table manually. However, static routes are removed from the routing table if the specified interface goes down, and are reinstated when the interface comes back up.

### Note

If you create a static route with an administrative distance greater than the administrative distance of the routing protocol running on the adaptive security appliance, then a route to the specified destination discovered by the routing protocol takes precedence over the static route. The static route is used only if the dynamically discovered route is removed from the routing table.

To configure a static route, see the following section:

- [Add/Edit a Static Route, page 20-3](#)

## Add/Edit a Static Route

To add or edit a static route, enter the following command:

Command	Purpose
<b>route</b> <i>if_name dest_ip mask gateway_ip</i> <i>[distance]</i>  <b>Example:</b> <pre>hostname(config)# route outside 10.10.10.0 255.255.255.0 192.168.1.1 [1]</pre>	<p>This enables you to add a static route.</p> <p>The <i>dest_ip</i> and <i>mask</i> is the IP address for the destination network and the <i>gateway_ip</i> is the address of the next-hop router. The addresses you specify for the static route are the addresses that are in the packet before entering the adaptive security appliance and performing NAT.</p> <p>The <i>Metric/distance</i> is the administrative distance for the route. The default is 1 if you do not specify a value. Administrative distance is a parameter used to compare routes among different routing protocols. The default administrative distance for static routes is 1, giving it precedence over routes discovered by dynamic routing protocols but not directly connect routes.</p> <p>The default administrative distance for routes discovered by OSPF is 110. If a static route has the same administrative distance as a dynamic route, the static routes take precedence. Connected routes always take precedence over static or dynamically discovered routes.</p>

## Configuring a Default Static Route

A default route identifies the gateway IP address to which the adaptive security appliance sends all IP packets for which it does not have a learned or static route. A default static route is simply a static route with 0.0.0.0/0 as the destination IP address. Routes that identify a specific destination take precedence over the default route.

**Note**

In ASA software Versions 7.0 and later, if you have two default routes configured on different interfaces that have different metrics, the connection to the ASA firewall that is made from the higher metric interface fails, but connections to the ASA firewall from the lower metric interface succeed as expected.

You can define up to three equal cost default route entries per device. Defining more than one equal cost default route entry causes the traffic sent to the default route to be distributed among the specified gateways. When defining more than one default route, you must specify the same interface for each entry.

If you attempt to define more than three equal cost default routes, or if you attempt to define a default route with a different interface than a previously defined default route, you receive the following message:

"ERROR: Cannot add route entry, possible conflict with existing routes."

You can define a separate default route for tunneled traffic along with the standard default route. When you create a default route with the **tunneled** option, all traffic from a tunnel terminating on the adaptive security appliance that cannot be routed using learned or static routes, is sent to this route. For traffic emerging from a tunnel, this route overrides over any other configured or learned default routes.

## Limitations on Configuring a Default Static Route

The following restrictions apply to default routes with the tunneled option:

- Do not enable unicast RPF (**ip verify reverse-path**) on the egress interface of tunneled route. Enabling Unicast RPF on the egress interface of a tunneled route causes the session to fail.
- Do not enable TCP intercept on the egress interface of the tunneled route. Doing so causes the session to fail.
- Do not use the VoIP inspection engines (CTIQBE, H.323, GTP, MGCP, RTSP, SIP, SKINNY), the DNS inspect engine, or the DCE RPC inspection engine with tunneled routes. These inspection engines ignore the tunneled route.

You cannot define more than one default route with the tunneled option; ECMP for tunneled traffic is not supported.

To add or edit a tunneled default static route, enter the following command:

Command	Purpose
<b>route</b> <i>if_name</i> 0.0.0.0 0.0.0.0 <i>gateway_ip</i> [distance   tunneled]	<p>This enables you to add a static route.</p> <p>The <i>dest_ip</i> and <i>mask</i> is the IP address for the destination network and the <i>gateway_ip</i> is the address of the next-hop router. The addresses you specify for the static route are the addresses that are in the packet before entering the adaptive security appliance and performing NAT.</p> <p>The <i>distance</i> is the administrative distance for the route. The default is 1 if you do not specify a value. Administrative distance is a parameter used to compare routes among different routing protocols. The default administrative distance for static routes is 1, giving it precedence over routes discovered by dynamic routing protocols but not directly connect routes. The default administrative distance for routes discovered by OSPF is 110. If a static route has the same administrative distance as a dynamic route, the static routes take precedence. Connected routes always take precedence over static or dynamically discovered routes.</p>

**Tip**

You can enter 0 0 instead of 0.0.0.0 0.0.0.0 for the destination network address and mask, for example:

```
hostname(config)# route outside 0 0 192.168.1 1
```

## Configuring IPv6 Default and Static Routes

The adaptive security appliance automatically routes IPv6 traffic between directly connected hosts if the interfaces to which the hosts are attached are enabled for IPv6 and the IPv6 ACLs allow the traffic.

To configure an IPv6 default route and static routes, perform the following steps:

### Detailed Steps

	Command	Purpose
<b>Step 1</b>	<b>ipv6 route</b> <i>if_name</i> ::/0 <i>next_hop_ipv6_addr</i>  <b>Example:</b> hostname(config)# ipv6 route inside 7fff::0/32 3FFE:1100:0:CC00::1	<p>This step adds a default IPv6 route.</p> <p>This example routes packets for network 7fff::0/32 to a networking device on the inside interface at 3FFE:1100:0:CC00::1</p> <p>The address ::/0 is the IPv6 equivalent of “any.”</p>
<b>Step 2</b>	<b>ipv6 route</b> <i>if_name</i> <i>destination</i> <i>next_hop_ipv6_addr</i> [ <i>admin_distance</i> ]  <b>Example:</b> hostname(config)# ipv6 route inside 7fff::0/32 3FFE:1100:0:CC00::1 [110]	<p>This step adds an IPv6 static route to the IPv6 routing table.</p> <p>This example routes packets for network 7fff::0/32 to a networking device on the inside interface at 3FFE:1100:0:CC00::1, and with an administrative distance of 110.</p>

**Note**

The **ipv6 route** command works the same way as the **route** command, which is used to define IPv4 static routes.

## Monitoring a Static or Default Route

One of the problems with static routes is that there is no inherent mechanism for determining if the route is up or down. They remain in the routing table even if the next hop gateway becomes unavailable. Static routes are only removed from the routing table if the associated interface on the adaptive security appliance goes down.

The static route tracking feature provides a method for tracking the availability of a static route and installing a backup route if the primary route should fail. This allows you to, for example, define a default route to an ISP gateway and a backup default route to a secondary ISP in case the primary ISP becomes unavailable.

The adaptive security appliance does this by associating a static route with a monitoring target that you define. It monitors the target using ICMP echo requests. If an echo reply is not received within a specified time period, the object is considered down and the associated route is removed from the routing table. A previously configured backup route is used in place of the removed route.

When selecting a monitoring target, you need to make sure it can respond to ICMP echo requests. The target can be any network object that you choose, but you should consider using the following:

- The ISP gateway (for dual ISP support) address
- The next hop gateway address (if you are concerned about the availability of the gateway)
- A server on the target network, such as a AAA server, that the adaptive security appliance needs to communicate with
- A persistent network object on the destination network (a desktop or notebook computer that may be shut down at night is not a good choice)

You can configure static route tracking for statically defined routes or default routes obtained through DHCP or PPPoE. You can only enable PPPoE clients on multiple interface with route tracking.

To configure static route tracking, perform the following steps:

## Detailed Steps

	Command	Purpose
Step 1	<b>sla monitor</b> <i>sla_id</i>  <b>Example:</b> hostname(config)# sla monitor <i>sla_id</i>	Configure the tracked object monitoring parameters by defining the monitoring process.  If you are configuring a new monitoring process, you enter sla monitor configuration mode.  If you are changing the monitoring parameters for an unscheduled monitoring process that already has a type defined, you automatically enter sla protocol configuration mode.
Step 2	<b>type echo protocol ipIcmpEcho</b> <i>target_ip</i> <b>interface</b> <i>if_name</i>  <b>Example:</b> hostname(config-sla-monitor)# type echo protocol ipIcmpEcho <i>target_ip</i> interface <i>if_name</i>	Specify the monitoring protocol.  If you are changing the monitoring parameters for an unscheduled monitoring process that already has a type defined, you automatically enter sla protocol configuration mode and cannot change this setting.  The <i>target_ip</i> is the IP address of the network object whose availability the tracking process monitors. While this object is available, the tracking process route is installed in the routing table. When this object becomes unavailable, the tracking process removed the route and the backup route is used in its place.
Step 3	<b>sla monitor</b> <i>sla_id</i>  <b>Example:</b> hostname(config)# sla monitor <i>sla_id</i>	Configure the tracked object monitoring parameters by defining the monitoring process.  If you are configuring a new monitoring process, you enter sla monitor configuration mode.  If you are changing the monitoring parameters for an unscheduled monitoring process that already has a type defined, you automatically enter sla protocol configuration mode.
Step 4	<b>type echo protocol ipIcmpEcho</b> <i>target_ip</i> <b>interface</b> <i>if_name</i>  <b>Example:</b> hostname(config-sla-monitor)# type echo protocol ipIcmpEcho <i>target_ip</i> interface <i>if_name</i>	Specify the monitoring protocol.  If you are changing the monitoring parameters for an unscheduled monitoring process that already has a type defined, you automatically enter sla protocol configuration mode and cannot change this setting.  The <i>target_ip</i> is the IP address of the network object whose availability the tracking process monitors. While this object is available, the tracking process route is installed in the routing table. When this object becomes unavailable, the tracking process removed the route and the backup route is used in its place.

	Command	Purpose
Step 5	<pre><b>sla monitor schedule</b> <i>sla_id</i> [<b>life</b> {<b>forever</b>   <b>seconds</b>}] [<b>start-time</b> {<i>hh:mm</i> [:<i>ss</i>] [<i>month day</i>   <i>day month</i>]   <b>pending</b>   <b>now</b>   <b>after</b> <i>hh:mm:ss</i>}] [<b>ageout</b> <i>seconds</i>] [<b>recurring</b>]</pre> <p><b>Example:</b></p> <pre>hostname(config)# sla monitor schedule <i>sla_id</i> [<b>life</b> {<b>forever</b>   <b>seconds</b>}] [<b>start-time</b> {<i>hh:mm</i>[:<i>ss</i>] [<i>month day</i>   <i>day month</i>]   <b>pending</b>   <b>now</b>   <b>after</b> <i>hh:mm:ss</i>}] [<b>ageout</b> <i>seconds</i>] [<b>recurring</b>]</pre>	<p>Schedule the monitoring process.</p> <p>Typically, you will use the <b>sla monitor schedule <i>sla_id</i> life forever start-time now</b> command for the monitoring schedule, and allow the monitoring configuration to determine how often the testing occurs.</p> <p>However, you can schedule this monitoring process to begin in the future and to only occur at specified times.</p>
Step 6	<pre><b>track</b> <i>track_id</i> <b>rtr</b> <i>sla_id</i> <b>reachability</b></pre> <p><b>Example:</b></p> <pre>hostname(config)# track <i>track_id</i> rtr <i>sla_id</i> reachability</pre>	<p>Associate a tracked static route with the SLA monitoring process.</p> <p>The <i>track_id</i> is a tracking number you assign with this command. The <i>sla_id</i> is the ID number of the SLA process.</p>
Step 7	<p>Do one of the following to define the static route to be installed in the routing table while the tracked object is reachable.</p> <p>These options allow you to track a static route, or default route obtained through DHCP or PPPOE.</p> <pre><b>route</b> <i>if_name</i> <i>dest_ip</i> <i>mask</i> <i>gateway_ip</i> [<i>admin_distance</i>] <b>track</b> <i>track_id</i></pre> <p><b>Example:</b></p> <pre>hostname(config)# route <i>if_name</i> <i>dest_ip</i> <i>mask</i> <i>gateway_ip</i> [<i>admin_distance</i>] track <i>track_id</i></pre> <pre>hostname(config)# interface <i>phy_if</i> hostname(config-if)# dhcp client route track <i>track_id</i> hostname(config-if)# ip address dhcp setroute hostname(config-if)# exit</pre> <pre>hostname(config)# interface <i>phy_if</i> hostname(config-if)# pppoe client route track <i>track_id</i> hostname(config-if)# ip address pppoe setroute hostname(config-if)# exit</pre>	<p>This option tracks a static route.</p> <p>You cannot use the <b>tunneled</b> option with the <b>route</b> command with static route tracking.</p> <p>This option tracks a default route obtained through DHCP.</p> <p>Remember that you must use the <b>setroute</b> argument with the <b>ip address dhcp</b> command to obtain the default route using DHCP.</p> <p>This option tracks a default route obtained through PPPoE.</p> <p>You must use the <b>setroute</b> argument with the <b>ip address pppoe</b> command to obtain the default route using PPPoE.</p>

## Configuration Examples for Static or Default Routes

The following example shows how to configure static routes:

### Step 1 Create a static route:

```
hostname(config)# route inside 10.1.1.0 255.255.255.0 10.1.2.45 1
```

In this step, a static route is created that sends all traffic destined for 10.1.1.0/24 to the router (10.1.2.45) connected to the inside interface.

- Step 2** Define three equal cost static routes that directs traffic to three different gateways on the outside interface, and adds a default route for tunneled traffic. The adaptive security appliance distributes the traffic among the specified gateways.

```
hostname(config)# route outside 10.10.10.0 255.255.255.0 192.168.1.1
hostname(config)# route outside 10.10.10.0 255.255.255.0 192.168.1.2
hostname(config)# route outside 10.10.10.0 255.255.255.0 192.168.1.3
hostname(config)# route outside 0 0 192.168.2.4 tunneled
```

Unencrypted traffic received by the adaptive security appliance for which there is no static or learned route is distributed among the gateways with the IP addresses 192.168.2.1, 192.168.2.2, and 192.168.2.3. Encrypted traffic received by the adaptive security appliance for which there is no static or learned route is passed to the gateway with the IP address 192.168.2.4.

## Feature History for Static and Default Routes

Table 20-1 lists each feature change and the platform release in which it was implemented.

**Table 20-1** Feature History for Static and Default Routes

Feature Name	Platform Releases	Feature Information
Routing	7.0(1)	The <b>route</b> command was introduced.  The <b>route</b> command was introduced to enter a static or default route for the specified interface.

# CHAPTER 21

## Defining Route Maps

---

This chapter describes route maps and includes the following sections:

- [Route Maps Overview, page 21-1](#)
- [Licensing Requirements for Route Maps, page 21-3](#)
- [Guidelines and Limitations, page 21-3](#)
- [Defining a Route Map, page 21-4](#)
- [Customizing a Route Map, page 21-4](#)
- [Configuration Example for Route Maps, page 21-6](#)
- [Feature History for Route Maps, page 21-6](#)

## Route Maps Overview

Route maps are used when redistributing routes into an OSPF, RIP, or EIGRP routing process. They are also used when generating a default route into an OSPF routing process. A route map defines which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process.

Route maps have many features in common with widely known access control lists (ACLs). These are some of the traits common to both mechanisms:

- They are an ordered sequence of individual statements, each has a permit or deny result. Evaluation of ACL or route maps consists of a list scan, in a predetermined order, and an evaluation of the criteria of each statement that matches. A list scan is aborted once the first statement match is found and an action associated with the statement match is performed.
- They are generic mechanisms—criteria matches and match interpretation are dictated by the way they are applied. The same route map applied to different tasks might be interpreted differently.

These are some of the differences between route maps and ACLs:

- Route maps frequently use ACLs as matching criteria.
- The main result from the evaluation of an access list is a yes or no answer—an ACL either permits or denies input data. Applied to redistribution, an ACL determines if a particular route can (route matches ACLs permit statement) or can not (matches deny statement) be redistributed. Typical route maps not only permit (some) redistributed routes but also modify information associated with the route, when it is redistributed into another protocol.
- Route maps are more flexible than ACLs and can verify routes based on criteria which ACLs can not verify. For example, a route map can verify if the type of route is internal.

- Each ACL ends with an implicit deny statement, by design convention; there is no similar convention for route maps. If the end of a route map is reached during matching attempts, the result depends on the specific application of the route map. Fortunately, route maps that are applied to redistribution behave the same way as ACLs: if the route does not match any clause in a route map then the route redistribution is denied, as if the route map contained deny statement at the end.

The dynamic protocol **redistribute** command allows you to apply a route map. In ASDM, this capability for redistribution can be found when you add or edit a new route map (see the [“Defining a Route Map” section on page 21-4](#)). Route maps are preferred if you intend to either modify route information during redistribution or if you need more powerful matching capability than an ACL can provide. If you simply need to selectively permit some routes based on their prefix or mask, we recommend that you use route map to map to an ACL (or equivalent prefix list) directly in the **redistribute** command. If you use a route map to selectively permit some routes based on their prefix or mask, you typically use more configuration commands to achieve the same goal.

**Note**

You must use a standard ACL as the match criterion for your route map. Using an extended ACL will not work, and your routes will never be redistributed.

We recommend that you number clauses in intervals of 10, to reserve numbering space in case you need to insert clauses in the future.

This section includes the following topics:

- [Permit and Deny Clauses](#)
- [Match and Set Clause Values](#)

## Permit and Deny Clauses

Route maps can have **permit** and **deny** clauses. In **route-map ospf-to-eigrp**, there is one deny clause (with sequence number 10) and two permit clauses. The deny clause rejects route matches from redistribution. Therefore, the following rules apply:

- If you use an ACL in a route map using a permit clause, routes that are permitted by the ACL are redistributed.
- If you use an ACL in a route map deny clause, routes that are permitted by the ACL are not redistributed.
- If you use an ACL in a route map permit or deny clause, and the ACL denies a route, then the route map clause match is not found and the next route-map clause is evaluated.

## Match and Set Clause Values

Each route map clause has two types of values:

- **match**—Selects routes to which this clause should be applied.
- **set**—Modifies information which will be redistributed into the target protocol.

For each route that is being redistributed, the router first evaluates the match criteria of a clause in the route map. If the match criteria succeed, then the route is redistributed or rejected as dictated by the permit or deny clause, and some of its attributes might be modified by the values set from the Set Value tab in ASDM or from the **set** commands. If the match criteria fail, then this clause is not applicable to

the route, and the software proceeds to evaluate the route against the next clause in the route map. Scanning of the route map continues until a clause is found whose **match** command(s), or Match Clause as set from the Match Clause tab in ASDM, match the route or until the end of the route map is reached.

A **match** or **set** value in each clause can be missed or repeated several times, if one of these conditions exists:

- If several **match** commands or Match Clause values in ASDM are present in a clause, all must succeed for a given route in order for that route to match the clause (in other words, the logical AND algorithm is applied for multiple match commands).
- If a **match** command or Match Clause value in ASDM refers to several objects in one command, either of them should match (the logical OR algorithm is applied). For example, in the **match ip address 101 121** command, a route is permitted if access list 101 or access list 121 permits it.
- If a **match** command or Match Clause value in ASDM is not present, all routes match the clause. In the previous example, all routes that reach clause 30 match; therefore, the end of the route map is never reached.
- If a **set** command, or Set Value in ASDM, is not present in a route map permit clause, then the route is redistributed without modification of its current attributes.

**Note**

Do not configure a **set** command in a route map deny clause because the deny clause prohibits route redistribution—there is no information to modify.

A route map clause without a **match** or **set** command, or Match or Set Value as set on the Match or Set Value tab in ASDM, performs an action. An empty permit clause allows a redistribution of the remaining routes without modification. An empty deny clause does not allow a redistribution of other routes (this is the default action if a route map is completely scanned but no explicit match is found).

## Licensing Requirements for Route Maps

Model	License Requirement
All models	Base License.

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single context mode.

### Firewall Mode Guidelines

Supported only in routed mode. Transparent mode is not supported.

### IPv6 Guidelines

Does not support IPv6.

# Defining a Route Map

When defining which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process, you must define a route map. This involves adding, editing, or deleting a route map.

To define a route map, enter the following command:

Command	Purpose
<code>route-map name {permit   deny}</code> <code>[sequence_number]</code>  <b>Example:</b> <code>hostname(config)# route-map name {permit}</code> <code>[12]</code>	Create the route map entry.  Route map entries are read in order. You can identify the order using the <i>sequence_number</i> option, or the adaptive security appliance uses the order in which you add the entries.

# Customizing a Route Map

This section describes how to customize the route map and includes the following topics:

- [Defining a Route to Match a Specific Destination Address, page 21-4](#)
- [Configuring the Metric Values for a Route Action, page 21-5](#)

# Defining a Route to Match a Specific Destination Address

To define a route to match a specified destination address, perform the following steps:

## Detailed Steps

	Command	Purpose
Step 1	<code>route-map name {permit   deny}</code> <code>[sequence_number]</code>  <b>Example:</b> <code>hostname(config)# route-map name {permit}</code> <code>[12]</code>	Creates the route map entry.  Route map entries are read in order. You can identify the order using the <i>sequence_number</i> option, or the adaptive security appliance uses the order in which you add the entries.
Step 2	Enter one of the following <b>match</b> commands to match routes to a specified destination address:  <code>match ip address acl_id [acl_id] [...]</code>  <b>Example:</b> <code>hostname(config-route-map)# match ip</code> <code>address acl_id [acl_id] [...]</code>	This allows you to match any routes that have a destination network that matches a standard ACL.  If you specify more than one ACL, then the route can match any of the ACLs.

Command	Purpose
<b>match metric</b> <i>metric_value</i>  <b>Example:</b> hostname(config-route-map)# <b>match metric</b> 200	This allows you to match any routes that have a specified metric.  The <i>metric_value</i> can be from 0 to 4294967295.
<b>match ip next-hop</b> <i>acl_id</i> [ <i>acl_id</i> ] [...]  <b>Example:</b> hostname(config-route-map)# <b>match ip next-hop</b> <i>acl_id</i> [ <i>acl_id</i> ] [...]	This allows you to match any routes that have a next hop router address that matches a standard ACL.  If you specify more than one ACL, then the route can match any of the ACLs.
<b>match interface</b> <i>if_name</i>  <b>Example:</b> hostname(config-route-map)# <b>match interface</b> <i>if_name</i>	This allows you to match any routes with the specified next hop interface.  If you specify more than one interface, then the route can match either interface.
<b>match ip route-source</b> <i>acl_id</i> [ <i>acl_id</i> ] [...]  <b>Example:</b> hostname(config-route-map)# <b>match ip route-source</b> <i>acl_id</i> [ <i>acl_id</i> ] [...]	This allows you to match any routes that have been advertised by routers that match a standard ACL.  If you specify more than one ACL, then the route can match any of the ACLs.
<b>match route-type</b> { <b>internal</b>   <b>external</b> [ <b>type-1</b>   <b>type-2</b> ]}  <b>Example:</b> hostname(config-route-map)# <b>match route-type</b> <b>internal type-1</b>	This allows you to match the route type.

## Configuring the Metric Values for a Route Action

If a route matches the **match** commands, then the following **set** commands determine the action to perform on the route before redistributing it.

To configure the metric value for a route action, perform the following steps:

### Detailed Steps

	Command	Purpose
Step 1	<b>route-map</b> <i>name</i> { <b>permit</b>   <b>deny</b> } [ <i>sequence_number</i> ]  <b>Example:</b> hostname(config)# <b>route-map</b> <i>name</i> { <b>permit</b> } [12]	Creates the route map entry.  Route map entries are read in order. You can identify the order using the <i>sequence_number</i> option, or the adaptive security appliance uses the order in which you add the entries.
Step 2	To set a metric for the route map, enter one or more of the following <b>set</b> commands:	

Command	Purpose
<b>set metric</b> <i>metric_value</i>  <b>Example:</b> hostname(config-route-map)# <b>set metric</b> 200	This allows you to set the metric value.  The <i>metric_value</i> can be a value between 0 and 294967295.
<b>set metric-type</b> { <b>type-1</b>   <b>type-2</b> }  <b>Example:</b> hostname(config-route-map)# <b>set metric-type</b> type-2	This allows you to set the metric type.  The <i>metric-type</i> can be type-1 or type-2.

## Configuration Example for Route Maps

The following example shows how to redistribute routes with a hop count equal to 1 into OSPF:

The adaptive security appliance redistributes these routes as external LSAs with a metric of 5 and a metric type of Type 1.

```
hostname(config)# route-map 1-to-2 permit
hostname(config-route-map)# match metric 1
hostname(config-route-map)# set metric 5
hostname(config-route-map)# set metric-type type-1
```

The following example shows how to redistribute the 10.1.1.0 static route into eigrp process 1 with the configured metric value:

```
hostname(config)# route outside 10.1.1.0 255.255.255.0 192.168.1.1
hostname(config-route-map)# access-list mymap2 line 1 standard permit 10.1.1.0
255.255.255.0
hostname(config-route-map)# route-map mymap2 permit 10
hostname(config-route-map)# match ip address mymap2
hostname(config-route-map)# router eigrp 1
hostname(config-route-map)# redistribute static metric 250 250 1 1 1 route-map mymap2
```

## Feature History for Route Maps

Table 21-1 lists each feature change and the platform release in which it was implemented.

Table 21-1 Feature History for Static and Default Routes

Feature Name	Platform Releases	Feature Information
Route mapping	7.0(1)	The <b>route-map</b> command was introduced.  The <b>route-map</b> command allows you to define a route map entry.
Enhanced support for static and dynamic route maps.	8.0(2)	Enhanced support for dynamic and static route maps was added.

## CHAPTER 22

# Configuring OSPF

---

This chapter describes how to configure the adaptive security appliance to route data, perform authentication, and redistribute routing information, using the Open Shortest Path First (OSPF) routing protocol.

The chapter includes the following sections:

- [Information About OSPF, page 22-1](#)
- [Licensing Requirements for OSPF, page 22-3](#)
- [Guidelines and Limitations, page 22-3](#)
- [Configuring OSPF, page 22-3](#)
- [Customizing OSPF, page 22-4](#)
- [Monitoring OSPF, page 22-16](#)
- [Configuration Example for OSPF, page 22-14](#)
- [Feature History for OSPF, page 22-17](#)

## Information About OSPF

OSPF is an interior gateway routing protocol that uses link states rather than distance vectors for path selection. OSPF propagates link-state advertisements rather than routing table updates. Because only LSAs are exchanged instead of the entire routing tables, OSPF networks converge more quickly than RIP networks.

OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area contains an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

The advantages of OSPF over RIP include the following:

- OSPF link-state database updates are sent less frequently than RIP updates, and the link-state database is updated instantly rather than gradually as stale information is timed out.
- Routing decisions are based on cost, which is an indication of the overhead required to send packets across a certain interface. The adaptive security appliance calculates the cost of an interface based on link bandwidth rather than the number of hops to the destination. The cost can be configured to specify preferred paths.

The disadvantage of shortest path first algorithms is that they require a lot of CPU cycles and memory.

The adaptive security appliance can run two processes of OSPF protocol simultaneously, on different sets of interfaces. You might want to run two processes if you have interfaces that use the same IP addresses (NAT allows these interfaces to coexist, but OSPF does not allow overlapping addresses). Or you might want to run one process on the inside, and another on the outside, and redistribute a subset of routes between the two processes. Similarly, you might need to segregate private addresses from public addresses.

You can redistribute routes into an OSPF routing process from another OSPF routing process, a RIP routing process, or from static and connected routes configured on OSPF-enabled interfaces.

The adaptive security appliance supports the following OSPF features:

- Support of intra-area, interarea, and external (Type I and Type II) routes.
- Support of a virtual link.
- OSPF LSA flooding.
- Authentication to OSPF packets (both password and MD5 authentication).
- Support for configuring the adaptive security appliance as a designated router or a designated backup router. The adaptive security appliance also can be set up as an ABR.
- Support for stub areas and not-so-stubby-areas.

Area boundary router Type-3 LSA filtering.

OSPF supports MD5 and clear text neighbor authentication. Authentication should be used with all routing protocols when possible because route redistribution between OSPF and other protocols (like RIP) can potentially be used by attackers to subvert routing information.

If NAT is used, if OSPF is operating on public and private areas, and if address filtering is required, then you need to run two OSPF processes—one process for the public areas and one for the private areas.

A router that has interfaces in multiple areas is called an Area Border Router (ABR). A router that acts as a gateway to redistribute traffic between routers using OSPF and routers using other routing protocols is called an Autonomous System Boundary Router (ASBR).

An ABR uses LSAs to send information about available routes to other OSPF routers. Using ABR Type 3 LSA filtering, you can have separate private and public areas with the adaptive security appliance acting as an ABR. Type 3 LSAs (inter-area routes) can be filtered from one area to other. This lets you use NAT and OSPF together without advertising private networks.

**Note**

Only Type 3 LSAs can be filtered. If you configure the adaptive security appliance as an ASBR in a private network, it will send Type 5 LSAs describing private networks, which will get flooded to the entire AS including public areas.

If NAT is employed but OSPF is only running in public areas, then routes to public networks can be redistributed inside the private network, either as default or Type 5 AS External LSAs. However, you need to configure static routes for the private networks protected by the adaptive security appliance. Also, you should not mix public and private networks on the same adaptive security appliance interface.

You can have two OSPF routing processes, one RIP routing process, and one EIGRP routing process running on the adaptive security appliance at the same time.

# Licensing Requirements for OSPF

Model	License Requirement
All models	Base License.

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single context mode.

### Firewall Mode Guidelines

Supported in routed mode only. Transparent mode is not supported.

### IPv6 Guidelines

Does not support IPv6.

## Configuring OSPF

This section describes how to enable an OSPF process on your system.

After you enable OSPF, you need to define a route map. For more information, see the [“Defining Route Maps” section on page 21-1](#). Then you generate a default route. For more information, see the [“Configuring Static and Default Routes” section on page 20-2](#).

After you have defined a route map for the OSPF process, you can customize the OSPF process to suit your particular needs. To learn how to customize the OSPF process on your system, see the [“Customizing OSPF” section on page 22-4](#).

To enable OSPF, you need to create an OSPF routing process, specify the range of IP addresses associated with the routing process, then assign area IDs associated with that range of IP addresses.

You can enable up to two OSPF process instances. Each OSPF process has its own associated areas and networks.

To enable OSPF, perform the following steps:

## Detailed Steps

	Command	Purpose
Step 1	<b>router ospf</b> <i>process_id</i>  <b>Example:</b> hostname(config)# router ospf 2	Creates an OSPF routing process and enters router configuration mode for this OSPF process.  The <i>process_id</i> is an internally used identifier for this routing process and can be any positive integer. This ID does not have to match the ID on any other device; it is for internal use only. You can use a maximum of two processes.  If there is only one OSPF process enabled on the adaptive security appliance, then that process is selected by default. You cannot change the OSPF process ID when editing an existing area.
Step 2	<b>network</b> <i>ip_address mask area area_id</i>  <b>Example:</b> hostname(config)# router ospf 2 hostname(config-router)# network 10.0.0.0 255.0.0.0 area 0	Defines the IP addresses on which OSPF runs and the area ID for that interface.  When adding a new area, enter the area ID. You can specify the area ID as either a decimal number or an IP address. Valid decimal values range from 0-4294967295. You cannot change the area ID when editing an existing area.

## Customizing OSPF

This section explains how to customize the OSPF process and includes the following topics:

- [Redistributing Routes Into OSPF, page 22-4](#)
- [Configuring OSPF Interface Parameters, page 22-8](#)
- [Configuring Route Summarization Between OSPF Areas, page 22-7](#)
- [Configuring OSPF Interface Parameters, page 22-8](#)
- [Configuring OSPF Area Parameters, page 22-10](#)
- [Configuring OSPF NSSA, page 22-11](#)
- [Configuring Route Calculation Timers, page 22-13](#)
- [Defining Static OSPF Neighbors, page 22-12](#)
- [Logging Neighbors Going Up or Down, page 22-14](#)
- [Restarting the OSPF Process, page 22-14](#)

## Redistributing Routes Into OSPF

The adaptive security appliance can control the redistribution of routes between OSPF routing processes.

### Note

If you want to redistribute a route by defining which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process, you must first generate a default route. See the “[Configuring Static and Default Routes](#)” section on [page 20-2](#) and then define a route map according to the “[Defining a Route Map](#)” section on [page 21-4](#).

To redistribute static, connected, RIP, or OSPF routes into an OSPF process, perform the following steps:

### Detailed Steps

	Command	Purpose
Step 1	<b>router ospf</b> <i>process_id</i>	Creates an OSPF routing process and enters router configuration mode for the OSPF process that you want to redistribute.
	<b>Example:</b> hostname(config)# router ospf 2	The <i>process_id</i> is an internally used identifier for this routing process and can be any positive integer. This ID does not have to match the ID on any other device; it is for internal use only. You can use a maximum of two processes.
Step 2	Do one of the following to redistribute the selected route type into the OSPF routing process:	
	<b>redistribute connected</b> [ <b>metric</b> <i>metric-value</i> ] [ <b>metric-type</b> { <b>type-1</b>   <b>type-2</b> }] [ <b>tag</b> <i>tag_value</i> ] [ <b>subnets</b> ] [ <b>route-map</b> <i>map_name</i> ]	Redistributes connected routes into the OSPF routing process.
	<b>Example:</b> hostname(config)# redistribute connected 5 type-1 route-map-practice	
	<b>redistribute static</b> [ <b>metric</b> <i>metric-value</i> ] [ <b>metric-type</b> { <b>type-1</b>   <b>type-2</b> }] [ <b>tag</b> <i>tag_value</i> ] [ <b>subnets</b> ] [ <b>route-map</b> <i>map_name</i> ]	Redistributes static routes into the OSPF routing process.
	<b>Example:</b> hostname(config)# redistribute static 5 type-1 route-map-practice	
	<b>redistribute ospf</b> <i>pid</i> [ <b>match</b> { <b>internal</b>   <b>external</b> [ <b>1</b>   <b>2</b> ]   <b>nssa-external</b> [ <b>1</b>   <b>2</b> ]}] [ <b>metric</b> <i>metric-value</i> ] [ <b>metric-type</b> { <b>type-1</b>   <b>type-2</b> }] [ <b>tag</b> <i>tag_value</i> ] [ <b>subnets</b> ] [ <b>route-map</b> <i>map_name</i> ]	Allows you to redistribute routes from an OSPF routing process into another OSPF routing process.
	<b>Example:</b> hostname(config)# route-map 1-to-2 permit hostname(config-route-map)# match metric 1 hostname(config-route-map)# set metric 5 hostname(config-route-map)# set metric-type type-1 hostname(config-route-map)# router ospf 2 hostname(config-router)# redistribute ospf 1 route-map 1-to-2	You can either use the <b>match</b> options in this command to match and set route properties, or you can use a route map. The <b>subnets</b> option does not have equivalents in the <b>route-map</b> command. If you use both a route map and <b>match</b> options in the <b>redistribute</b> command, then they must match.  The example shows route redistribution from OSPF process 1 into OSPF process 2 by matching routes with a metric equal to 1. The adaptive security appliance redistributes these routes as external LSAs with a metric of 5 and a metric type of Type 1.

Command	Purpose
<b>redistribute rip</b> [ <b>metric</b> <i>metric-value</i> ] [ <b>metric-type</b> { <b>type-1</b>   <b>type-2</b> }] [ <b>tag</b> <i>tag_value</i> ] [ <b>subnets</b> ] [ <b>route-map</b> <i>map_name</i> ]  <b>Example:</b> hostname(config)# redistribute rip 5 hostname(config-route-map)# match metric 1 hostname(config-route-map)# set metric 5 hostname(config-route-map)# set metric-type type-1 hostname(config-router)# redistribute ospf 1 route-map 1-to-2	Allows you to redistribute routes from a RIP routing process into the OSPF routing process.
<b>redistribute eigrp as-num</b> [ <b>metric</b> <i>metric-value</i> ] [ <b>metric-type</b> { <b>type-1</b>   <b>type-2</b> }] [ <b>tag</b> <i>tag_value</i> ] [ <b>subnets</b> ] [ <b>route-map</b> <i>map_name</i> ]  <b>Example:</b> hostname(config)# redistribute eigrp 2 hostname(config-route-map)# match metric 1 hostname(config-route-map)# set metric 5 hostname(config-route-map)# set metric-type type-1 hostname(config-router)# redistribute ospf 1 route-map 1-to-2	Allows you to redistribute routes from an EIGRP routing process into the OSPF routing process.

## Configuring Route Summarization When Redistributing Routes into OSPF

When routes from other protocols are redistributed into OSPF, each route is advertised individually in an external LSA. However, you can configure the adaptive security appliance to advertise a single route for all the redistributed routes that are covered by a specified network address and mask. This configuration decreases the size of the OSPF link-state database.

Routes that match the specified IP Address mask pair can be suppressed. The Tag value can be used as a match value for controlling redistribution through route maps.

To configure the software advertisement on one summary route for all redistributed routes covered by a network address and mask, perform the following steps:

### Detailed Steps

	Command	Purpose
Step 1	<b>router ospf</b> <i>process_id</i>	Creates an OSPF routing process and enters router configuration mode for this OSPF process.
	<b>Example:</b> hostname(config)# router ospf 1	The <i>process_id</i> is an internally used identifier for this routing process and can be any positive integer. This ID does not have to match the ID on any other device; it is for internal use only. You can use a maximum of two processes.
Step 2	<b>summary-address</b> <i>ip_address mask</i> [ <b>not-advertise</b> ] [ <b>tag tag</b> ]	Sets the summary address.
	<b>Example:</b> hostname(config)# router ospf 1 hostname(config-router)# summary-address 10.1.0.0 255.255.0.0	In this example, the summary address 10.1.0.0 includes addresses 10.1.1.0, 10.1.2.0, 10.1.3.0, and so on. Only the 10.1.0.0 address is advertised in an external link-state advertisement.

## Configuring Route Summarization Between OSPF Areas

Route summarization is the consolidation of advertised addresses. This feature causes a single summary route to be advertised to other areas by an area boundary router. In OSPF, an area boundary router advertises networks in one area into another area. If the network numbers in an area are assigned in a way such that they are contiguous, you can configure the area boundary router to advertise a summary route that covers all the individual networks within the area that fall into the specified range.

To define an address range for route summarization, perform the following steps:

### Detailed Steps

	Command	Purpose
Step 1	<b>router ospf</b> <i>process_id</i>	Creates an OSPF routing process and enters router configuration mode for this OSPF process.
	<b>Example:</b> hostname(config)# router ospf 1	The <i>process_id</i> is an internally used identifier for this routing process. It can be any positive integer. This ID does not have to match the ID on any other device; it is for internal use only. You can use a maximum of two processes.
Step 2	<b>area</b> <i>area-id</i> <b>range</b> <i>ip-address mask</i> [ <b>advertise</b>   <b>not-advertise</b> ]	Sets the address range.
	<b>Example:</b> hostname(config)# router ospf 1 hostname(config-router)# area 17 range 12.1.0.0 255.255.0.0	In this example, the address range is set between OSPF areas.

## Configuring OSPF Interface Parameters

You can alter some interface-specific OSPF parameters as necessary.

### Prerequisites

You are not required to alter any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: **ospf hello-interval**, **ospf dead-interval**, and **ospf authentication-key**. Be sure that if you configure any of these parameters, the configurations for all routers on your network have compatible values.

To configure OSPF interface parameters, perform the following steps:

### Detailed Steps

	Command	Purpose
Step 1	<b>router ospf</b> <i>process_id</i>	Creates an OSPF routing process and enters router configuration mode for the OSPF process that you want to redistribute.
	<b>Example:</b> hostname(config)# router ospf 2	The <i>process_id</i> is an internally used identifier for this routing process and can be any positive integer. This ID does not have to match the ID on any other device; it is for internal use only. You can use a maximum of two processes.
Step 2	<b>network</b> <i>ip_address mask area</i> <i>area_id</i>	Defines the IP addresses on which OSPF runs and the area ID for that interface.
	<b>Example:</b> hostname(config)# router ospf 2 hostname(config-router)# network 10.0.0.0 255.0.0.0 area 0	
Step 3	hostname(config)# <b>interface</b> <i>interface_name</i>	Allows you to enter interface configuration mode.
	<b>Example:</b> hostname(config)# interface my_interface	
Step 4	Do one of the following to configure optional OSPF interface parameters:	
	<b>ospf authentication</b> [ <b>message-digest</b>   <b>null</b> ]	Specifies the authentication type for an interface.
	<b>Example:</b> hostname(config-interface)# ospf authentication message-digest	

Command	Purpose
<b>ospf authentication-key</b> <i>key</i>  <b>Example:</b> <pre>hostname(config-interface)# ospf authentication-key cisco</pre>	<p>Allows you to assign a password to be used by neighboring OSPF routers on a network segment that is using the OSPF simple password authentication.</p> <p>The <i>key</i> can be any continuous string of characters up to 8 bytes in length.</p> <p>The password created by this command is used as a key that is inserted directly into the OSPF header when the adaptive security appliance software originates routing protocol packets. A separate password can be assigned to each network on a per-interface basis. All neighboring routers on the same network must have the same password to be able to exchange OSPF information.</p>
<b>ospf cost</b> <i>cost</i>  <b>Example:</b> <pre>hostname(config-interface)# ospf cost 20</pre>	<p>Allows you to explicitly specify the cost of sending a packet on an OSPF interface. The <i>cost</i> is an integer from 1 to 65535.</p> <p>In this example, the cost is set to 20.</p>
<b>ospf dead-interval</b> <i>seconds</i>  <b>Example:</b> <pre>hostname(config-interface)# ospf dead-interval 40</pre>	<p>Allows you to set the number of seconds that a device must wait before it declares a neighbor OSPF router down because it has not received a hello packet. The value must be the same for all nodes on the network.</p> <p>In this example, the dead interval is set to 40.</p>
<b>ospf hello-interval</b> <i>seconds</i>  <b>Example:</b> <pre>hostname(config-interface)# ospf hello-interval 10</pre>	<p>Allows you to specify the length of time between the hello packets that the adaptive security appliance sends on an OSPF interface. The value must be the same for all nodes on the network.</p> <p>In this example, the hello interval is set to 10.</p>
<b>ospf message-digest-key</b> <i>key_id md5 key</i>  <b>Example:</b> <pre>hostname(config-interface)# ospf message-digest-key 1 md5 cisco</pre>	<p>Enables OSPF MD5 authentication.</p> <p>The following values can be set:</p> <ul style="list-style-type: none"> <li><i>key_id</i>—An identifier in the range from 1 to 255.</li> <li><i>key</i>—Alphanumeric password of up to 16 bytes.</li> </ul> <p>Usually, one key per interface is used to generate authentication information when sending packets and to authenticate incoming packets. The same key identifier on the neighbor router must have the same key value.</p> <p>We recommend that you not keep more than one key per interface. Every time you add a new key, you should remove the old key to prevent the local system from continuing to communicate with a hostile system that knows the old key. Removing the old key also reduces overhead during rollover.</p>
<b>ospf priority</b> <i>number_value</i>  <b>Example:</b> <pre>hostname(config-interface)# ospf priority 20</pre>	<p>Allows you to set the priority to help determine the OSPF designated router for a network.</p> <p>The <i>number_value</i> is between 0 to 255.</p> <p>In this example, the priority number value is set to 20.</p>

Command	Purpose
<b>ospf retransmit-interval</b> <i>seconds</i>  <b>Example:</b> <pre>hostname(config-interface)# ospf retransmit-interval seconds</pre>	<p>Allows you to specify the number of seconds between LSA retransmissions for adjacencies belonging to an OSPF interface.</p> <p>The value for <i>seconds</i> must be greater than the expected round-trip delay between any two routers on the attached network. The range is from 1 to 65535 seconds. The default value is 5 seconds.</p> <p>In this example, the retransmit-interval value is set to 15.</p>
<b>ospf transmit-delay</b> <i>seconds</i>  <b>Example:</b> <pre>hostname(config-interface)# ospf transmit-delay 5</pre>	<p>Sets the estimated number of seconds required to send a link-state update packet on an OSPF interface. The <i>seconds</i> value is from 1 to 65535 seconds. The default value is 1 second.</p> <p>In this example, the transmit-delay is 5 seconds.</p>
<b>ospf network point-to-point non-broadcast</b>  <b>Example:</b> <pre>hostname(config-interface)# ospf network point-to-point non-broadcast</pre>	<p>Specifies the interface as a point-to-point, non-broadcast network.</p> <p>When you designate an interface as point-to-point, nonbroadcast, you must manually define the OSPF neighbor; dynamic neighbor discovery is not possible. See the <a href="#">“Defining Static OSPF Neighbors”</a> section on page 22-12, for more information. Additionally, you can only define one OSPF neighbor on that interface.</p>

## Configuring OSPF Area Parameters

You can configure several OSPF area parameters. These area parameters (shown in the following task list) include setting authentication, defining stub areas, and assigning specific costs to the default summary route. Authentication provides password-based protection against unauthorized access to an area.

Stub areas are areas into which information on external routes is not sent. Instead, there is a default external route generated by the ABR, into the stub area for destinations outside the autonomous system. To take advantage of the OSPF stub area support, default routing must be used in the stub area. To further reduce the number of LSAs sent into a stub area, you can configure the **no-summary** keyword of the **area stub** command on the ABR to prevent it from sending summary link advertisement (LSA Type 3) into the stub area.

To specify area parameters for your network, perform the following steps:

## Detailed Steps

	Command	Purpose
Step 1	<b>router ospf</b> <i>process_id</i>	Creates an OSPF routing process and enters router configuration mode for the OSPF process that you want to redistribute.
	<b>Example:</b> hostname(config)# router ospf 2	The <i>process_id</i> is an internally used identifier for this routing process and can be any positive integer. This ID does not have to match the ID on any other device; it is for internal use only. You can use a maximum of two processes.
Step 2	Do one of the following to configure optional OSPF area parameters:	
	<b>area</b> <i>area-id</i> <b>authentication</b>	Enables authentication for an OSPF area.
	<b>Example:</b> hostname(config-router)# area 0 authentication	
	<b>area</b> <i>area-id</i> <b>authentication message-digest</b>	Enables MD5 authentication for an OSPF area.
	<b>Example:</b> hostname(config-router)# area 0 authentication message-digest	

## Configuring OSPF NSSA

The OSPF implementation of an NSSA is similar to an OSPF stub area. NSSA does not flood Type 5 external LSAs from the core into the area, but it can import autonomous system external routes in a limited way within the area.

NSSA imports Type 7 autonomous system external routes within an NSSA area by redistribution. These Type 7 LSAs are translated into Type 5 LSAs by NSSA ABRs, which are flooded throughout the whole routing domain. Summarization and filtering are supported during the translation.

You can simplify administration if you are an ISP or a network administrator that must connect a central site using OSPF to a remote site that is using a different routing protocol using NSSA.

Before the implementation of NSSA, the connection between the corporate site border router and the remote router could not be run as an OSPF stub area because routes for the remote site could not be redistributed into the stub area, and two routing protocols needed to be maintained. A simple protocol such as RIP was usually run and handled the redistribution. With NSSA, you can extend OSPF to cover the remote connection by defining the area between the corporate router and the remote router as an NSSA.

Before you use this feature, consider these guidelines:

- You can set a Type 7 default route that can be used to reach external destinations. When configured, the router generates a Type 7 default into the NSSA or the NSSA area boundary router.
- Every router within the same area must agree that the area is NSSA; otherwise, the routers will not be able to communicate.

To specify area parameters for your network as needed to configure OSPF NSSA, perform the following steps:

### Detailed Steps

Command	Purpose
<b>Step 1</b> <code>router ospf <i>process_id</i></code>  <b>Example:</b> <code>hostname(config)# router ospf 2</code>	Creates an OSPF routing process and enters router configuration mode for the OSPF process that you want to redistribute.  The <i>process_id</i> is an internally used identifier for this routing process. It can be any positive integer. This ID does not have to match the ID on any other device; it is for internal use only. You can use a maximum of two processes.
<b>Step 2</b> Do one of the following to configure optional OSPF NSSA parameters:	
<code>area <i>area-id</i> nssa [no-redistribution] [default-information-originate]</code>  <b>Example:</b> <code>hostname(config-router)# area 0 nssa</code>	Defines an NSSA area.
<code>summary-address <i>ip_address mask</i> [not-advertise] [tag <i>tag</i>]</code>  <b>Example:</b> <code>hostname(config)# router ospf 1 hostname(config-router)# summary-address 10.1.0.0 255.255.0.0</code>	Sets the summary address and helps reduce the size of the routing table. Using this command for OSPF causes an OSPF ASBR to advertise one external route as an aggregate for all redistributed routes that are covered by the address.  In this example, the summary address 10.1.0.0 includes addresses 10.1.1.0, 10.1.2.0, 10.1.3.0, and so on. Only the 10.1.0.0 address is advertised in an external link-state advertisement

**Note** OSPF does not support summary-address 0.0.0.0 0.0.0.0.

## Defining Static OSPF Neighbors

You need to define static OSPF neighbors to advertise OSPF routes over a point-to-point, non-broadcast network. This lets you broadcast OSPF advertisements across an existing VPN connection without having to encapsulate the advertisements in a GRE tunnel.

Before you begin, you must create a static route to the OSPF neighbor. See [Chapter 20, “Configuring Static and Default Routes,”](#) for more information about creating static routes.

To define a static OSPF neighbor, perform the following steps:

## Detailed Steps

	Command	Purpose
Step 1	<b>router ospf</b> <i>process_id</i>  <b>Example:</b> hostname(config)# router ospf 2	Creates an OSPF routing process and enters router configuration mode for this OSPF process.  The <i>process_id</i> is an internally used identifier for this routing process and can be any positive integer. This ID does not have to match the ID on any other device; it is for internal use only. You can use a maximum of two processes.
Step 2	<b>neighbor</b> <i>addr</i> [ <b>interface</b> <i>if_name</i> ]  <b>Example:</b> hostname(config-router)# neighbor 255.255.0.0 [interface <i>my_interface</i> ]	Defines the OSPF neighborhood.  The <i>addr</i> argument is the IP address of the OSPF neighbor. The <i>if_name</i> is the interface used to communicate with the neighbor. If the OSPF neighbor is not on the same network as any of the directly-connected interfaces, you must specify the <b>interface</b> .

## Configuring Route Calculation Timers

You can configure the delay time between when OSPF receives a topology change and when it starts an SPF calculation. You also can configure the hold time between two consecutive SPF calculations.

To configure route calculation timers, perform the following steps:

## Detailed Steps

	Command	Purpose
Step 1	<b>router ospf</b> <i>process_id</i>  <b>Example:</b> hostname(config)# router ospf 2	Creates an OSPF routing process and enters router configuration mode for this OSPF process.  The <i>process_id</i> is an internally used identifier for this routing process and can be any positive integer. This ID does not have to match the ID on any other device; it is for internal use only. You can use a maximum of two processes.
Step 2	<b>timers spf</b> <i>spf-delay</i> <i>spf-holdtime</i>  <b>Example:</b> hostname(config-router)# timers spf 10 120	Configures the route calculation times.  The <i>spf-delay</i> is the delay time (in seconds) between when OSPF receives a topology change and when it starts an SPF calculation. It can be an integer from 0 to 65535. The default time is 5 seconds. A value of 0 means that there is no delay; that is, the SPF calculation is started immediately.  The <i>spf-holdtime</i> is the minimum time (in seconds) between two consecutive SPF calculations. It can be an integer from 0 to 65535. The default time is 10 seconds. A value of 0 means that there is no delay; that is, two SPF calculations can be done, one immediately after the other.

## Logging Neighbors Going Up or Down

By default, a system message is generated when an OSPF neighbor goes up or down.

Configure this command if you want to know about OSPF neighbors going up or down without turning on the **debug ospf adjacency** command. The **log-adj-changes** router configuration command provides a higher level view of the peer relationship with less output. Configure the **log-adj-changes detail** command if you want to see messages for each state change.

To log neighbors going up or down, perform the following steps:

### Detailed Steps

	Command	Purpose
Step 1	<b>router ospf</b> <i>process_id</i>  <b>Example:</b> hostname(config)# router ospf 2	Creates an OSPF routing process and enters router configuration mode for this OSPF process.  The <i>process_id</i> is an internally used identifier for this routing process and can be any positive integer. This ID does not have to match the ID on any other device; it is for internal use only. You can use a maximum of two processes.
Step 2	<b>log-adj-changes</b> [ <b>detail</b> ]  <b>Example:</b> hostname(config-router)# log-adj-changes [detail]	This step configures logging for neighbors going up or down.

## Restarting the OSPF Process

To remove the entire OSPF configuration that you have enabled, enter the following command:

Command	Purpose
<b>clear ospf</b> <i>pid</i> { <b>process</b>   <b>redistribution</b>   <b>counters</b> [ <b>neighbor</b> [ <i>neighbor-interface</i> ] [ <i>neighbor-id</i> ]]}	Removes the entire OSPF configuration that you have enabled. After the configuration is cleared, you must reconfigure OSPF using the <b>router ospf</b> command.
<b>Example:</b> hostname(config)# clear ospf	

## Configuration Example for OSPF

The following example shows how to enable and configure OSPF with various optional processes:

**Step 1** Enable OSPF:

```
hostname(config)# router ospf 2
hostname(config-router)# network 10.0.0.0 255.0.0.0 area 0
```

**Step 2** (Optional) Redistribute routes from one OSPF process to another OSPF process:

```

hostname(config)# route-map 1-to-2 permit
hostname(config-route-map)# match metric 1
hostname(config-route-map)# set metric 5
hostname(config-route-map)# set metric-type type-1
hostname(config-route-map)# router ospf 2
hostname(config-router)# redistribute ospf 1 route-map 1-to-2

```

**Step 3** Configure OSPF interface parameters (optional):

```

hostname(config)# router ospf 2
hostname(config-router)# network 10.0.0.0 255.0.0.0 area 0
hostname(config-router)# interface inside
hostname(config-interface)# ospf cost 20
hostname(config-interface)# ospf retransmit-interval 15
hostname(config-interface)# ospf transmit-delay 10
hostname(config-interface)# ospf priority 20
hostname(config-interface)# ospf hello-interval 10
hostname(config-interface)# ospf dead-interval 40
hostname(config-interface)# ospf authentication-key cisco
hostname(config-interface)# ospf message-digest-key 1 md5 cisco
hostname(config-interface)# ospf authentication message-digest

```

**Step 4** (Optional) Configure OSPF area parameters:

```

hostname(config)# router ospf 2
hostname(config-router)# area 0 authentication
hostname(config-router)# area 0 authentication message-digest
hostname(config-router)# area 17 stub
hostname(config-router)# area 17 default-cost 20

```

**Step 5** (Optional) Configure the route calculation timers and show the log neighbor up and down messages:

```

hostname(config-router)# timers spf 10 120
hostname(config-router)# log-adj-changes [detail]

```

**Step 6** Restart the OSPF process:

```

hostname(config)# clear ospf pid {process | redistribution | counters
[neighbor [neighbor-interface] [neighbor-id]]}

```

**Step 7** (Optional) Show the results of your OSPF configuration:

The following is sample output from the **show ospf** command:

```

hostname(config)# show ospf

Routing Process "ospf 2" with ID 10.1.89.2 and Domain ID 0.0.0.2
Supports only single TOS(TOS0) routes
Supports opaque LSA
SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
Minimum LSA interval 5 secs. Minimum LSA arrival 1 secs
Number of external LSA 5. Checksum Sum 0x 26da6
Number of opaque AS LSA 0. Checksum Sum 0x      0
Number of DCbitless external and opaque AS LSA 0
Number of DoNotAge external and opaque AS LSA 0
Number of areas in this router is 1. 1 normal 0 stub 0 nssa
External flood list length 0
  Area BACKBONE(0)
    Number of interfaces in this area is 1
    Area has no authentication
    SPF algorithm executed 2 times
    Area ranges are
    Number of LSA 5. Checksum Sum 0x 209a3
    Number of opaque link LSA 0. Checksum Sum 0x      0

```

```

Number of DCbitless LSA 0
Number of indication LSA 0
Number of DoNotAge LSA 0
Flood list length 0

```

## Monitoring OSPF

You can display specific statistics such as the contents of IP routing tables, caches, and databases. You can also use the information provided to determine resource utilization and solve network problems. You can also display information about node reachability and discover the routing path that your device packets are taking through the network.

To monitor or display various OSPF routing statistics, enter one of the following commands:

Command	Purpose
<b>show ospf</b> [ <i>process-id</i> [ <i>area-id</i> ]]	Displays general information about OSPF routing processes.
<b>show ospf border-routers</b>	Displays the internal OSPF routing table entries to the ABR and ASBR.
<b>show ospf</b> [ <i>process-id</i> [ <i>area-id</i> ]] <b>database</b>	Displays lists of information related to the OSPF database for a specific router.
<b>show ospf flood-list</b> <i>if-name</i>	<p>Displays a list of LSAs waiting to be flooded over an interface (to observe OSPF packet pacing).</p> <p>OSPF update packets are automatically paced so they are not sent less than 33 milliseconds apart. Without pacing, some update packets could get lost in situations where the link is slow, a neighbor could not receive the updates quickly enough, or the router could run out of buffer space. For example, without pacing packets might be dropped if either of the following topologies exist:</p> <ul style="list-style-type: none"> <li>• A fast router is connected to a slower router over a point-to-point link.</li> <li>• During flooding, several neighbors send updates to a single router at the same time.</li> </ul> <p>Pacing is also used between resends to increase efficiency and minimize lost retransmissions. You also can display the LSAs waiting to be sent out an interface. The benefit of the pacing is that OSPF update and retransmission packets are sent more efficiently.</p> <p>There are no configuration tasks for this feature; it occurs automatically.</p>
<b>show ospf interface</b> [ <i>if_name</i> ]	Displays OSPF-related interface information.

Command	Purpose
<b>show ospf neighbor</b> [ <i>interface-name</i> ] [ <i>neighbor-id</i> ] [ <b>detail</b> ]	Displays OSPF neighbor information on a per-interface basis.
<b>show ospf request-list</b> <i>neighbor if_name</i>	Displays a list of all LSAs requested by a router.
<b>show ospf retransmission-list</b> <i>neighbor if_name</i>	Displays a list of all LSAs waiting to be resent.
<b>show ospf</b> [ <i>process-id</i> ] <b>summary-address</b>	Displays a list of all summary address redistribution information configured under an OSPF process.
<b>show ospf</b> [ <i>process-id</i> ] <b>virtual-links</b>	Displays OSPF-related virtual links information.

## Feature History for OSPF

Table 22-1 lists each feature change and the platform release in which it was implemented.

**Table 22-1** Feature History for Static and Default Routes

Feature Name	Platform Releases	Feature Information
OSPF Support	7.0(1)	Support was added for route data, perform authentication, redistribute and monitor routing information, using the Open Shortest Path First (OSPF) routing protocol.  The <b>route ospf</b> command was introduced to route data, perform authentication, redistribute and monitor routing information, using the Open Shortest Path First (OSPF) routing protocol.

# CHAPTER 23

## Configuring RIP

---

This chapter describes how to configure the adaptive security appliance to route data, perform authentication, and redistribute routing information, using the Routing Information Protocol (RIP).

The chapter includes the following sections:

- [Overview, page 23-1](#)
- [Licensing Requirements for RIP, page 23-2](#)
- [Guidelines and Limitations, page 23-3](#)
- [Configuring RIP, page 23-3](#)
- [Customizing RIP, page 23-4](#)
- [Monitoring RIP, page 23-11](#)
- [Configuration Example for RIP, page 23-11](#)
- [Feature History for RIP, page 23-12](#)

## Overview

The Routing Information Protocol, or RIP, as it is more commonly called, is one of the most enduring of all routing protocols. RIP has four basic components: routing update process, RIP routing metrics, routing stability, and routing timers. Devices that support RIP send routing-update messages at regular intervals and when the network topology changes. These RIP packets contain information about the networks that the devices can reach, as well as the number of routers or gateways that a packet must travel through to reach the destination address. RIP generates more traffic than OSPF, but is easier to configure.

RIP is a distance-vector routing protocol that uses hop count as the metric for path selection. When RIP is enabled on an interface, the interface exchanges RIP broadcasts with neighboring devices to dynamically learn about and advertise routes.

The adaptive security appliance support both RIP Version 1 and RIP Version 2. RIP Version 1 does not send the subnet mask with the routing update. RIP Version 2 sends the subnet mask with the routing update and supports variable-length subnet masks. Additionally, RIP Version 2 supports neighbor authentication when routing updates are exchanged. This authentication ensures that the adaptive security appliance receives reliable routing information from a trusted source.

RIP has advantages over static routes because the initial configuration is simple, and you do not need to update the configuration when the topology changes. The disadvantage to RIP is that there is more network and processing overhead than static routing.

## Routing Update Process

RIP sends routing-update messages at regular intervals and when the network topology changes. When a router receives a routing update that includes changes to an entry, it updates its routing table to reflect the new route. The metric value for the path is increased by 1, and the sender is indicated as the next hop. RIP routers maintain only the best route (the route with the lowest metric value) to a destination. After updating its routing table, the router immediately begins transmitting routing updates to inform other network routers of the change. These updates are sent independently of the regularly scheduled updates that RIP routers send.

## RIP Routing Metric

RIP uses a single routing metric (hop count) to measure the distance between the source and a destination network. Each hop in a path from source to destination is assigned a hop count value, which is typically 1. When a router receives a routing update that contains a new or changed destination network entry, the router adds 1 to the metric value indicated in the update and enters the network in the routing table. The IP address of the sender is used as the next hop.

## RIP Stability Features

RIP prevents routing loops from continuing indefinitely by implementing a limit on the number of hops allowed in a path from the source to a destination. The maximum number of hops in a path is 15. If a router receives a routing update that contains a new or changed entry, and if increasing the metric value by 1 causes the metric to be infinity (that is, 16), the network destination is considered unreachable. The downside of this stability feature is that it limits the maximum diameter of a RIP network to less than 16 hops.

RIP includes a number of other stability features that are common to many routing protocols. These features are designed to provide stability despite potentially rapid changes in network topology. For example, RIP implements the split horizon and hold-down mechanisms to prevent incorrect routing information from being propagated.

## RIP Timers

RIP uses numerous timers to regulate its performance. These include a routing-update timer, a route-timeout timer, and a route-flush timer. The routing-update timer clocks the interval between periodic routing updates. Generally, it is set to 30 seconds, with a small random amount of time added whenever the timer is reset. This is done to help prevent congestion, which could result from all routers simultaneously attempting to update their neighbors. Each routing table entry has a route-timeout timer associated with it. When the route-timeout timer expires, the route is marked invalid but is retained in the table until the route-flush timer expires.

## Licensing Requirements for RIP

Model	License Requirement
All models	Base License.

# Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

## Context Mode Guidelines

Supported in single and multiple context mode.

## Firewall Mode Guidelines

Supported in routed and transparent mode.

## IPv6 Guidelines

Does not support IPv6.

## Additional Guidelines

The following information applies to RIP Version 2 only:

- If using neighbor authentication, the authentication key and key ID must be the same on all neighbor devices that provide RIP Version 2 updates to the interface.
- With RIP Version 2, the adaptive security appliance transmits and receives default route updates using the multicast address 224.0.0.9. In passive mode, it receives route updates at that address.
- When RIP Version 2 is configured on an interface, the multicast address 224.0.0.9 is registered on that interface. When a RIP Version 2 configuration is removed from an interface, that multicast address is unregistered.

## Limitations

RIP has the following limitations:

- The adaptive security appliance cannot pass RIP updates between interfaces.
- RIP Version 1 does not support variable-length subnet masks.
- RIP has a maximum hop count of 15. A route with a hop count greater than 15 is considered unreachable.
- RIP convergence is relatively slow compared to other routing protocols.
- You can only enable a single RIP process on the adaptive security appliance.

# Configuring RIP

This section describes how to enable and restart the RIP process on the adaptive security appliance.

After you have enabled RIP, see the [“Customizing RIP” section on page 23-4](#), to learn how to customize the RIP process on the adaptive security appliance.

### Note

If you want to redistribute a route by defining which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process, you must first generate a default route. For information, see the [“Configuring a Default Static Route” section on page 20-4](#) and then define a route map. For information, see the [“Defining a Route Map” section on page 21-4](#).

## Enabling RIP

You can only enable one RIP routing process on the adaptive security appliance. After you enable the RIP routing process, you must define the interfaces that will participate in that routing process using the **network** command. By default, the adaptive security appliance sends RIP Version 1 updates and accepts RIP Version 1 and Version 2 updates.

To enable the RIP routing process, enter the following command:

Command	Purpose
<b>router rip</b>	Starts the RIP routing process and places you in router configuration mode.
<b>Example:</b> hostname(config)# router rip	Use the <b>no router rip</b> command to remove the entire RIP configuration that you have enabled. After the configuration is cleared, you must reconfigure RIP using the <b>router rip</b> command.

## Customizing RIP

This section describes how to configure RIP and includes the following topics:

- [Configure the RIP Version, page 23-5](#)
- [Configuring Interfaces for RIP, page 23-6](#)
- [Configuring the RIP Send and Receive Version on an Interface, page 23-6](#)
- [Configuring Route Summarization, page 23-7](#)
- [Filtering Networks in RIP, page 23-8](#)
- [Redistributing Routes into the RIP Routing Process, page 23-8](#)
- [Enabling RIP Authentication, page 23-9](#)
- [Restarting the RIP Process, page 23-10](#)

## Configure the RIP Version

To specify the version of RIP used by the adaptive security appliance, perform the following steps:

### Detailed Steps

	Command	Purpose
Step 1	<b>router rip</b>  <b>Example:</b> hostname(config)# router rip	Starts the RIP routing process and places you in router configuration mode.
Step 2	<b>network network_address</b>  <b>Example:</b> hostname(config)# router rip hostname(config-router)# network 10.0.0.0	Specifies the interfaces that will participate in the RIP routing process.  If an interface belongs to a network defined by this command, the interface will participate in the RIP routing process. If an interface does not belong to a network defined by this command, the interface will not send or receive RIP updates.
Step 3	Enter one of the following numbers to customize an interface to participate in RIP routing:  <b>version [1   2]</b>  <b>Example:</b> hostname(config-router)# version [1]	Specifies the version of RIP used by the adaptive security appliance.  You can override this setting on a per-interface basis.  In this example, Version 1 is entered.

## Configuring Interfaces for RIP

If you have an interface that you do not want to participate in RIP routing, but that is attached to a network that you want advertised, you can configure the network (using a **network** command) that covers the network the interface is attached to, and configure the passive interfaces (using the **passive-interface** command) to prevent that interface from sending RIP. Additionally, you can specify the version of RIP that is used by the adaptive security appliance for updates.

To configure interfaces for RIP, perform the following steps:

### Detailed Steps

	Command	Purpose
Step 1	<b>router rip</b>  <b>Example:</b> hostname(config)# router rip	Starts the RIP routing process and places you in router configuration mode.
Step 2	<b>network network_address</b>  <b>Example:</b> hostname(config)# router rip hostname(config-router)# network 10.0.0.0	Specifies the interfaces that will participate in the RIP routing process.  If an interface belongs to a network defined by this command, the interface will participate in the RIP routing process. If an interface does not belong to a network defined by this command, it will not send or receive RIP updates.
Step 3	<b>passive-interface [default   if_name]</b>  <b>Example:</b> hostname(config-router):# passive-interface [default]	Specifies an interface to operate in passive mode.  Using the <b>default</b> keyword causes all interfaces to operate in passive mode. Specifying an interface name sets only that interface to passive mode. In passive mode, RIP routing updates are accepted by, but not sent out of, the specified interface. You can enter this command for each interface that you want to set to passive mode.

## Configuring the RIP Send and Receive Version on an Interface

You can override the globally-set version of RIP that the adaptive security appliance uses to send and receive RIP updates on a per-interface basis.

To configure the RIP version for sending and receiving updates, perform the following steps:

### Detailed Steps

	Command	Purpose
Step 1	<b>interface phy_if</b>  <b>Example:</b> hostname(config)# interface phy_if	Enters interface configuration mode for the interface that you are configuring.
Step 2	Do one of the following to send or receive RIP updates on a per-interface basis.	

Command	Purpose
<b>rip send version {[1] [2]}</b>	Specifies the version of RIP to use when sending RIP updates out of the interface.
<b>Example:</b> hostname(config-if)# rip send version 1	In this example, Version 1 is selected.
<b>rip receive version {[1] [2]}</b>	Specifies the version of RIP advertisements permitted to be received by an interface.
<b>Example:</b> hostname(config-if)# rip receive version 2	In this example, Version 2 is selected. RIP updates received on the interface that do not match the allowed version are dropped.

## Configuring Route Summarization

### Note

RIP Version 1 always uses automatic route summarization. You cannot disable this feature for RIP Version 1. RIP Version 2 uses automatic route summarization by default.

The RIP routing process summarizes on network number boundaries, which can cause routing problems if you have noncontiguous networks.

For example, if you have a router with the networks 192.168.1.0, 192.168.2.0, and 192.168.3.0 connected to it, and those networks all participate in RIP, the RIP routing process creates the summary address 192.168.0.0 for those routes. If an additional router is added to the network with the networks 192.168.10.0 and 192.168.11.0, and those networks participate in RIP, they will also be summarized as 192.168.0.0. To prevent the possibility of traffic being routed to the wrong location, you should disable automatic route summarization on the routers that are creating conflicting summary addresses.

Because RIP Version 1 always uses automatic route summarization, and RIP Version 2 always uses automatic route summarization by default, when configuring automatic route summarization, you only need to disable it.

To disable automatic route summarization, enter the following command:

### Detailed Steps

	Command	Purpose
<b>Step 1</b>	<b>router rip</b>	Enables the RIP routing process and places you in router configuration mode.
	<b>Example:</b> hostname(config)# router rip	
<b>Step 2</b>	<b>no auto-summarize</b>	Disables automatic route summarization.
	<b>Example:</b> hostname(config-router):# no auto-summarize	

## Filtering Networks in RIP

To filter the networks received in updates, perform the following steps:

**Note**

Before you begin, you must create a standard access list that permits the networks that you want the RIP process to allow in the routing table and denies the networks that you want the RIP process to discard.

### Detailed Steps

	Command	Purpose
Step 1	<b>router rip</b>  <b>Example:</b> hostname(config)# router rip	Enables the RIP routing process and places you in router configuration mode.
Step 2	<b>distribute-list acl in [interface if_name]</b> <b>distribute-list acl out [connected   eigrp   interface if_name   ospf   rip   static]</b>  <b>Example:</b> hostname(config-router)# distribute-list acl2 in [interface interface1] hostname(config-router)# distribute-list acl3 out [connected]	Filters the networks sent in updates.  You can specify an interface to apply the filter to only those updates that are received or sent by that interface. You can enter this command for each interface to which you want to apply a filter. If you do not specify an interface name, the filter is applied to all RIP updates.

## Redistributing Routes into the RIP Routing Process

You can redistribute routes from the OSPF, EIGRP, static, and connected routing processes into the RIP routing process.

**Note**

Before you begin this procedure, you must create a route-map to further define which routes from the specified routing protocol are redistributed in to the RIP routing process. See [Chapter 21, “Defining Route Maps,”](#) for more information about creating a route map.

To redistribute a routes into the RIP routing process, enter one of the following commands:

Command	Purpose
Choose one of the following to redistribute the selected route type into the RIP routing process. You must specify the RIP metric values in the <b>redistribute</b> command if you do not have a <b>default-metric</b> command in the RIP router configuration.	
<b>redistribute connected</b> [metric <metric-value>   transparent] [route-map <route-map-name>]  <b>Example:</b> <pre>hostname(config-router): # redistribute connected [metric &lt;metric-value&gt;   transparent] [route-map &lt;route-map-name&gt;]</pre>	Redistributes connected routes into the RIP routing process.
<b>redistribute static</b> [metric {metric_value   transparent}] [route-map map_name]  <b>Example:</b> <pre>hostname(config-router):# redistribute static [metric {metric_value   transparent}] [route-map map_name]</pre>	Redistributes static routes into the EIGRP routing process.
<b>redistribute ospf pid</b> [match {internal   external [1   2]   nssa-external [1   2]}] [metric {metric_value   transparent}] [route-map map_name]  <b>Example:</b> <pre>hostname(config-router):# redistribute ospf pid [match {internal   external [1   2]   nssa-external [1   2]}] [metric {metric_value   transparent}] [route-map map_name]</pre>	Redistributes routes from an OSPF routing process into the RIP routing process.
<b>redistribute eigrp as-num</b> [metric {metric_value   transparent}] [route-map map_name]  <b>Example:</b> <pre>hostname(config-router):# redistribute eigrp as-num [metric {metric_value   transparent}] [route-map map_name]</pre>	Redistributes routes from an EIGRP routing process into the RIP routing process.

## Enabling RIP Authentication

### Note

The adaptive security appliance supports RIP message authentication for RIP Version 2 messages.

RIP route authentication provides MD5 authentication of routing updates from the RIP routing protocol. The MD5 keyed digest in each RIP packet prevents the introduction of unauthorized or false routing messages from unapproved sources.

RIP route authentication is configured on a per-interface basis. All RIP neighbors on interfaces configured for RIP message authentication must be configured with the same authentication mode and key for adjacencies to be established.

**Note**

Before you can enable RIP route authentication, you must enable RIP.

To enable RIP authentication on an interface, perform the following steps:

**Detailed Steps**

	Command	Purpose
<b>Step 1</b>	<b>router rip</b> <i>as-num</i>  <b>Example:</b> hostname(config)# router rip 2	Creates the RIP routing process and enters router configuration mode for this RIP process.  The <i>as-num</i> argument is the autonomous system number of the RIP routing process.
<b>Step 2</b>	<b>interface</b> <i>phy_if</i>  <b>Example:</b> hostname(config)# interface <i>phy_if</i>	Enters interface configuration mode for the interface on which you are configuring RIP message authentication.
<b>Step 3</b>	<b>rip authentication mode</b> { <b>text</b>   <b>md5</b> }  <b>Example:</b> hostname(config-if)# rip authentication mode md5	Sets the authentication mode. By default, text authentication is used. We recommend that you use MD5 authentication.
<b>Step 4</b>	<b>rip authentication key</b> <i>key</i> <b>key-id</b> <i>key-id</i>  <b>Example:</b> hostname(config-if)# rip authentication key <i>cisco</i> key-id 200	Configures the authentication key used by the MD5 algorithm.  The <i>key</i> argument can include up to 16 characters.  The <i>key-id</i> argument is a number from 0 to 255.

## Restarting the RIP Process

To remove the entire RIP configuration, enter the following command:

Command	Purpose
<b>clear rip</b> <i>pid</i> { <b>process</b>   <b>redistribution</b>   <b>counters</b> [ <b>neighbor</b> [ <i>neighbor-interface</i> ] [ <i>neighbor-id</i> ]]}	Removes the entire RIP configuration that you have enabled. After the configuration is cleared, you must reconfigure RIP again using the <b>router rip</b> command.
<b>Example:</b> hostname(config)# clear ospf	

# Monitoring RIP

We recommend that you only use the **debug** commands to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC.

Debugging output is assigned high priority in the CPU process and can render the adaptive security appliance unusable. It is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect performance. For examples and descriptions of the command output, see the *Cisco ASA 5500 Series Command Reference*.

To monitor or debug various RIP routing statistics, enter one of the following commands:

Command	Purpose
<b>Monitoring RIP Routing</b>	
<b>show rip database</b>	Display the contents of the RIP routing database.
<b>show running-config router rip</b>	Displays the RIP commands.
<b>Debugging RIP</b>	
<b>debug rip events</b>	Displays RIP processing events.
<b>debug rip database</b>	Displays RIP database events.

## Configuration Example for RIP

The following example shows how to enable and configure RIP with various optional processes:

- 
- Step 1** Enable RIP:
- ```
hostname(config)# router rip 2
```
- Step 2** Configure a default route into RIP:
- ```
hostname(config-router)# default-information originate
```
- Step 3** Specify the version of RIP to use:
- ```
hostname(config-router)# version [1]
```
- Step 4** Specify the interfaces that will participate in the RIP routing process:
- ```
hostname(config-router)# network 225.25.25.225
```
- Step 5** Specify an interface to operate in passive mode:
- ```
hostname(config-router)# passive-interface [default]
```
- Step 6** Redistribute a connected route into the RIP routing process:
- ```
hostname(config-router)# redistribute connected [metric bandwidth delay reliability  
loading mtu] [route-map map_name]
```

# Feature History for RIP

Table 23-1 lists each feature change and the platform release in which it was implemented.

**Table 23-1**      *Feature History for RIP*

Feature Name	Releases	Feature Information
RIP Support	7.0(1)	Support for routing data, performing authentication, and redistributing and monitoring routing information using the Routing Information Protocol (RIP).  The <b>route rip</b> command was introduced.  The <b>route rip</b> command is introduced to route data, perform authentication, redistribute and monitor routing information, using the Routing Information Protocol (RIP).

# CHAPTER 24

## Configuring EIGRP

---

This chapter describes how to configure the adaptive security appliance to route data, perform authentication, and redistribute routing information, using the Enhanced Interior Gateway Routing Protocol (EIGRP).

The chapter includes the following sections:

- [Overview, page 24-1](#)
- [Licensing Requirements for EIGRP, page 24-2](#)
- [Guidelines and Limitations, page 24-2](#)
- [Enabling EIGRP, page 24-3](#)
- [Customizing EIGRP, page 24-5](#)
- [Monitoring EIGRP, page 24-17](#)
- [Configuration Example for EIGRP, page 24-18](#)
- [Feature History for EIGRP, page 24-19](#)

## Overview

EIGRP is an enhanced version of IGRP developed by Cisco. Unlike IGRP and RIP, EIGRP does not send out periodic route updates. EIGRP updates are sent out only when the network topology changes. Key capabilities that distinguish EIGRP from other routing protocols include fast convergence, support for variable-length subnet mask, support for partial updates, and support for multiple network layer protocols.

A router running EIGRP stores all the neighbor routing tables so that it can quickly adapt to alternate routes. If no appropriate route exists, EIGRP queries its neighbors to discover an alternate route. These queries propagate until an alternate route is found. Its support for variable-length subnet masks permits routes to be automatically summarized on a network number boundary. In addition, EIGRP can be configured to summarize on any bit boundary at any interface. EIGRP does not make periodic updates. Instead, it sends partial updates only when the metric for a route changes. Propagation of partial updates is automatically bounded so that only those routers that need the information are updated. As a result of these two capabilities, EIGRP consumes significantly less bandwidth than IGRP.

Neighbor discovery is the process that the adaptive security appliance uses to dynamically learn of other routers on directly attached networks. EIGRP routers send out multicast hello packets to announce their presence on the network. When the adaptive security appliance receives a hello packet from a new

neighbor, it sends its topology table to the neighbor with an initialization bit set. When the neighbor receives the topology update with the initialization bit set, the neighbor sends its topology table back to the adaptive security appliance.

The hello packets are sent out as multicast messages. No response is expected to a hello message. The exception to this is for statically defined neighbors. If you use the **neighbor** command, or configure the Hello Interval in ASDM, to configure a neighbor, the hello messages sent to that neighbor are sent as unicast messages. Routing updates and acknowledgements are sent out as unicast messages.

Once this neighbor relationship is established, routing updates are not exchanged unless there is a change in the network topology. The neighbor relationship is maintained through the hello packets. Each hello packet received from a neighbor contains a hold time. This is the time in which the adaptive security appliance can expect to receive a hello packet from that neighbor. If the adaptive security appliance does not receive a hello packet from that neighbor within the hold time advertised by that neighbor, the adaptive security appliance considers that neighbor to be unavailable.

The EIGRP protocol uses four key algorithm technologies, four key technologies, including neighbor discover/recovery, Reliable Transport Protocol (RTP), and the fourth one, DUAL being important for route computations. DUAL saves all routes to a destination in the topology table, not just the least-cost route. The least-cost route is inserted into the routing table. The other routes remain in the topology table. If the main route fails, another route is chosen from the feasible successors. A successor is a neighboring router used for packet forwarding that has a least-cost path to a destination. The feasibility calculation guarantees that the path is not part of a routing loop.

If a feasible successor is not found in the topology table, a route recomputation must occur. During route recomputation, DUAL queries the EIGRP neighbors for a route, who in turn query their neighbors. Routers that do not have a feasible successor for the route return an unreachable message.

During route recomputation, DUAL marks the route as active. By default, the adaptive security appliance waits for three minutes to receive a response from its neighbors. If the adaptive security appliance does not receive a response from a neighbor, the route is marked as stuck-in-active. All routes in the topology table that point to the unresponsive neighbor as a feasibility successor are removed.

**Note**

EIGRP neighbor relationships are not supported through the IPSec tunnel without a GRE tunnel.

## Licensing Requirements for EIGRP

Model	License Requirement
All models	Base License.

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single context mode.

### Firewall Mode Guidelines

Supported only in routed mode. Transparent mode is not supported.

**IPv6 Guidelines**

Does not support IPv6.

## Configuring EIGRP

This section explains how to enable the EIGRP process on your system. After you have enabled EIGRP, see the following sections to learn how to customize the EIGRP process on your system.

- [Enabling EIGRP, page 24-3](#)
- [Enabling EIGRP Stub Routing, page 24-4](#)

## Enabling EIGRP

You can only enable one EIGRP routing process on the adaptive security appliance.

To enable EIGRP, perform the following steps:

### Detailed Steps

	Command	Purpose
Step 1	<b>router eigrp</b> <i>as-num</i>	Creates an EIGRP routing process and enters router configuration mode for this EIGRP process.
	<b>Example:</b> hostname(config)# router eigrp 2	The <i>as-num</i> argument is the autonomous system number of the EIGRP routing process.
Step 2	<b>network</b> <i>ip-addr</i> [ <i>mask</i> ]	Configures the interfaces and networks that participate in EIGRP routing. You can configure one or more <b>network</b> statements with this command.
	<b>Example:</b> hostname(config)# router eigrp 2 hostname(config-router)# network 10.0.0.0 255.0.0.0	Directly-connected and static networks that fall within the defined network are advertised by the adaptive security appliance. Additionally, only interfaces with an IP address that fall within the defined network participate in the EIGRP routing process.  If you have an interface that you do not want to have participate in EIGRP routing, but that is attached to a network that you want advertised, see the <a href="#">“Configuring Interfaces for EIGRP”</a> section on <a href="#">page 24-6</a> .

## Enabling EIGRP Stub Routing

You can enable, and configure the adaptive security appliance as an EIGRP stub router. Stub routing decreases memory and processing requirements on the adaptive security appliance. As a stub router, the adaptive security appliance does not need to maintain a complete EIGRP routing table because it forwards all nonlocal traffic to a distribution router. Generally, the distribution router need not send anything more than a default route to the stub router.

Only specified routes are propagated from the stub router to the distribution router. As a stub router, the adaptive security appliance responds to all queries for summaries, connected routes, redistributed static routes, external routes, and internal routes with the message “inaccessible.” When the adaptive security appliance is configured as a stub, it sends a special peer information packet to all neighboring routers to report its status as a stub router. Any neighbor that receives a packet informing it of the stub status will not query the stub router for any routes, and a router that has a stub peer will not query that peer. The stub router depends on the distribution router to send the correct updates to all peers.

To enable the adaptive security appliance as an EIGRP stub routing process, perform the following steps:

### Detailed Steps

	Command	Purpose
Step 1	<b>router eigrp</b> <i>as-num</i>	Creates an EIGRP routing process and enters router configuration mode for this EIGRP process.
	<b>Example:</b> hostname(config)# router eigrp 2	The <i>as-num</i> argument is the autonomous system number of the EIGRP routing process.
Step 2	<b>network</b> <i>ip-addr</i> [ <i>mask</i> ]	Configures the interfaces and networks that participate in EIGRP routing. You can configure one or more <b>network</b> statements with this command.
	<b>Example:</b> hostname(config)# router eigrp 2 hostname(config-router)# network 10.0.0.0 255.0.0.0	Directly-connected and static networks that fall within the defined network are advertised by the adaptive security appliance. Additionally, only interfaces with an IP address that fall within the defined network participate in the EIGRP routing process.
		If you have an interface that you do not want to have participate in EIGRP routing, but that is attached to a network that you want advertised, see the section <a href="#">“Configuring Passive Interfaces”</a> section on page 24-8.
Step 3	<b>eigrp stub</b> { <b>receive-only</b>   [ <b>connected</b> ] [ <b>redistributed</b> ] [ <b>static</b> ] [ <b>summary</b> ]}	Configures the stub routing process. You must specify which networks are advertised by the stub routing process to the distribution router. Static and connected networks are not automatically redistributed into the stub routing process.
	<b>Example:</b> hostname(config)# router eigrp 2 hostname(config-router)# network 10.0.0.0 255.0.0.0 hostname(config-router)# eigrp stub {receive-only   [connected] [ <b>redistributed</b> ] [ <b>static</b> ] [ <b>summary</b> ]}	

#### Note

A stub routing process does not maintain a full topology table. At a minimum, stub routing needs a default route to a distribution router, which makes the routing decisions.

# Customizing EIGRP

This section describes how to customize the EIGRP routing and includes the following topics:

- [Defining a Network for an EIGRP Routing Process, page 24-5](#)
- [Configuring Interfaces for EIGRP, page 24-6](#)
- [Configuring Passive Interfaces, page 24-8](#)
- [Configuring the Summary Aggregate Addresses on Interfaces, page 24-8](#)
- [Changing the Interface Delay Value, page 24-9](#)
- [Enabling EIGRP Authentication on an Interface, page 24-9](#)
- [Defining an EIGRP Neighbor, page 24-11](#)
- [Redistributing Routes Into EIGRP, page 24-11](#)
- [Filtering Networks in EIGRP, page 24-13](#)
- [Customizing the EIGRP Hello Interval and Hold Time, page 24-14](#)
- [Disabling Automatic Route Summarization, page 24-15](#)
- [Configuring Default Information in EIGRP, page 24-15](#)
- [Disabling EIGRP Split Horizon, page 24-16](#)
- [Restarting the EIGRP Process, page 24-17](#)

## Defining a Network for an EIGRP Routing Process

The Network table lets you specify the networks used by the EIGRP routing process. For an interface to participate in EIGRP routing, it must fall within the range of addresses defined by the network entries. For directly connected and static networks to be advertised, they must also fall within the range of the network entries.

The Network table displays the networks configured for the EIGRP routing process. Each row of the table displays the network address and associated mask configured for the specified EIGRP routing process.

To add or define a network, perform the following steps:

## Detailed Steps

	Command	Purpose
Step 1	<b>router eigrp</b> <i>as-num</i>	Creates an EIGRP routing process and enters router configuration mode for this EIGRP process.
	<b>Example:</b> hostname(config)# router eigrp 2	The <i>as-num</i> argument is the autonomous system number of the EIGRP routing process.
Step 2	<b>network</b> <i>ip-addr</i> [ <i>mask</i> ]	Configures the interfaces and networks that participate in EIGRP routing. You can configure one or more <b>network</b> statements with this command.
	<b>Example:</b> hostname(config)# router eigrp 2 hostname(config-router)# network 10.0.0.0 255.0.0.0	Directly-connected and static networks that fall within the defined network are advertised by the adaptive security appliance. Additionally, only interfaces with an IP address that fall within the defined network participate in the EIGRP routing process.  If you have an interface that you do not want to have participate in EIGRP routing, but that is attached to a network that you want advertised, see the section <a href="#">“Configuring Passive Interfaces”</a> section on page 24-8.

## Configuring Interfaces for EIGRP

If you have an interface that you do not want to have participate in EIGRP routing, but that is attached to a network that you want advertised, you can configure a **network** command that covers the network to which the interface is attached, and use the **passive-interface** command to prevent that interface from sending or receiving EIGRP updates.

To configure interfaces for EIGRP, perform the following steps:

## Detailed Steps

	Command	Purpose
Step 1	<b>router eigrp</b> <i>as-num</i>	Creates an EIGRP routing process and enters router configuration mode for this EIGRP process.
	<b>Example:</b> hostname(config)# router eigrp 2	The <i>as-num</i> argument is the autonomous system number of the EIGRP routing process.
Step 2	hostname(config-router)# <b>network</b> <i>ip-addr</i> [ <i>mask</i> ]	Configures the interfaces and networks that participate in EIGRP routing. You can configure one or more network statements with this command.
	<b>Example:</b> hostname(config)# router eigrp 2 hostname(config-router)# network 10.0.0.0 255.0.0.0	Directly-connected and static networks that fall within the defined network are advertised by the adaptive security appliance. Additionally, only interfaces with an IP address that fall within the defined network participate in the EIGRP routing process.  If you have an interface that you do not want to have participate in EIGRP routing, but that is attached to a network that you want advertised, see the section <a href="#">“Defining a Network for an EIGRP Routing Process”</a> section on page 24-5.

## Step 3

Command	Purpose
(Optional) Do one of the following to customize an interface to participate in EIGRP routing:	
<b>no default-information {in   out   WORD}</b>  <b>Example:</b> <pre>hostname(config)# router eigrp 2 hostname(config-router)# network 10.0.0.0 255.0.0.0 hostname(config-router)# no default-information {in   out   WORD}</pre>	<p>Allows you to control the sending or receiving of candidate default route information.</p> <p>Entering the <b>no default-information in</b> command causes the candidate default route bit to be blocked on received routes. Entering the <b>no default-information out</b> command disables the setting of the default route bit in advertised routes.</p> <p>See the <a href="#">“Configuring Default Information in EIGRP”</a> section on page 24-15 for more information on this particular option.</p>
<b>authentication mode eigrp as-num md5</b>  <b>Example:</b> <pre>hostname(config)# authentication mode eigrp 2 md5</pre>	<p>Enables MD5 authentication of EIGRP packets.</p> <p>The <i>as-num</i> argument is the autonomous system number of the EIGRP routing process configured on the adaptive security appliance. If EIGRP is not enabled or if you enter the wrong number, the adaptive security appliance returns the following error message:</p> <pre>% System(100) specified does not exist</pre> <p>See the <a href="#">“Enabling EIGRP Authentication on an Interface”</a> section on page 24-9 for more information on this particular option.</p>
<b>delay value</b>  <b>Example:</b> <pre>hostname(config-if)# delay 200</pre>	<p>The <i>value</i> entered is in tens of microseconds. To set the delay for 2000 microseconds, you enter a <i>value</i> of 200.</p> <p>To view the delay value assigned to an interface, use the <b>show interface</b> command.</p> <p>See the <a href="#">“Changing the Interface Delay Value”</a> section on page 24-9 for more information on this particular option.</p>
<b>hello-interval eigrp as-num seconds</b>  <b>Example:</b> <pre>hostname(config)# hello-interval eigrp 2 60</pre>	<p>Allows you to change the hello interval. See the <a href="#">“Customizing the EIGRP Hello Interval and Hold Time”</a> section on page 24-14 for more information on this particular option.</p>
<b>hold-time eigrp as-num seconds</b>  <b>Example:</b> <pre>hostname(config)# hold-time eigrp 2 60</pre>	<p>Allows you to change the hold time. See the <a href="#">“Customizing the EIGRP Hello Interval and Hold Time”</a> section on page 24-14 for more information on this particular option.</p>

## Configuring Passive Interfaces

You can configure one or more interfaces as passive interfaces. In EIGRP, a passive interface does not send or receive routing updates.

To configure passive interfaces, perform the following steps:

### Detailed Steps

	Command	Purpose
Step 1	<b>router eigrp</b> <i>as-num</i>	Creates an EIGRP routing process and enters router configuration mode for this EIGRP process.
	<b>Example:</b> hostname(config)# router eigrp 2	The <i>as-num</i> argument is the autonomous system number of the EIGRP routing process.
Step 2	hostname(config-router)# <b>network</b> <i>ip-addr</i> [ <i>mask</i> ]	Configures the interfaces and networks that participate in EIGRP routing. You can configure one or more <b>network</b> statements with this command.
	<b>Example:</b> hostname(config)# router eigrp 2 hostname(config-router)# network 10.0.0.0 255.0.0.0	Directly-connected and static networks that fall within the defined network are advertised by the adaptive security appliance. Additionally, only interfaces with an IP address that fall within the defined network participate in the EIGRP routing process.
		If you have an interface that you do not want to have participate in EIGRP routing, but that is attached to a network that you want advertised, see the <a href="#">“Defining a Network for an EIGRP Routing Process”</a> section on page 24-5.
Step 3	<b>passive-interface</b> { <b>default</b>   <i>if-name</i> }	Prevents an interface from sending or receiving EIGRP routing message.
	<b>Example:</b> hostname(config)# router eigrp 2 hostname(config-router)# network 10.0.0.0 255.0.0.0 hostname(config-router)# passive-interface {default}	Using the <b>default</b> keyword disables EIGRP routing updates on all interfaces. Specifying an interface name, as defined by the <b>nameif</b> command, disables EIGRP routing updates on the specified interface. You can use multiple <b>passive-interface</b> commands in your EIGRP router configuration.

## Configuring the Summary Aggregate Addresses on Interfaces

You can configure a summary addresses on a per-interface basis. You need to manually define summary addresses if you want to create summary addresses that do not occur at a network number boundary or if you want to use summary addresses on a adaptive security appliance with automatic route summarization disabled. If any more specific routes are in the routing table, EIGRP will advertise the summary address out the interface with a metric equal to the minimum of all more specific routes.

To create a summary address, perform the following steps:

## Detailed Steps

	Command	Purpose
Step 1	<b>interface</b> <i>phy_if</i>	Enters interface configuration mode for the interface on which you are changing the delay value used by EIGRP.
	<b>Example:</b> hostname(config)# <b>interface</b> <i>phy_if</i>	
Step 2	<b>summary-address eigrp</b> <i>as-num address mask [distance]</i>	Creates the summary address.  By default, EIGRP summary addresses that you define have an administrative distance of 5. You can change this value by specifying the optional <i>distance</i> argument in the <b>summary-address</b> command.
	<b>Example:</b> hostname(config-if)# <b>summary-address eigrp</b> <i>2 address mask [20]</i>	

## Changing the Interface Delay Value

The interface delay value is used in EIGRP distance calculations. You can modify this value on a per-interface basis.

To change the interface delay value, perform the following steps:

## Detailed Steps

	Command	Purpose
Step 1	<b>interface</b> <i>phy_if</i>	Enters interface configuration mode for the interface on which you are changing the delay value used by EIGRP.
	<b>Example:</b> hostname(config)# <b>interface</b> <i>phy_if</i>	
Step 2	<b>delay</b> <i>value</i>	The <i>value</i> entered is in tens of microseconds. To set the delay for 2000 microseconds, you enter a <i>value</i> of 200.
	<b>Example:</b> hostname(config-if)# <b>delay</b> <i>200</i>	To view the delay value assigned to an interface, use the <b>show interface</b> command.

## Enabling EIGRP Authentication on an Interface

EIGRP route authentication provides MD5 authentication of routing updates from the EIGRP routing protocol. The MD5 keyed digest in each EIGRP packet prevents the introduction of unauthorized or false routing messages from unapproved sources.

EIGRP route authentication is configured on a per-interface basis. All EIGRP neighbors on interfaces configured for EIGRP message authentication must be configured with the same authentication mode and key for adjacencies to be established.

### Note

Before you can enable EIGRP route authentication, you must enable EIGRP.

To enable EIGRP authentication on an interface, perform the following steps:

### Detailed Steps

Step 1	<b>router eigrp</b> <i>as-num</i>  <b>Example:</b> hostname(config)# <b>router eigrp</b> 2	Creates an EIGRP routing process and enters router configuration mode for this EIGRP process.  The <i>as-num</i> argument is the autonomous system number of the EIGRP routing process.
Step 2	<b>network</b> <i>ip-addr</i> [ <i>mask</i> ]  <b>Example:</b> hostname(config)# <b>router eigrp</b> 2 hostname(config-router)# <b>network</b> 10.0.0.0 255.0.0.0	Configures the interfaces and networks that participate in EIGRP routing. You can configure one or more network statements with this command.  Directly-connected and static networks that fall within the defined network are advertised by the adaptive security appliance. Additionally, only interfaces with an IP address that fall within the defined network participate in the EIGRP routing process.  If you have an interface that you do not want to have participate in EIGRP routing, but that is attached to a network that you want advertised, see the <a href="#">“Configuring EIGRP” section on page 24-3</a> .
Step 3	<b>interface</b> <i>phy_if</i>  <b>Example:</b> hostname(config)# <b>interface</b> <i>phy_if</i>	Enters interface configuration mode for the interface on which you are configuring EIGRP message authentication.
Step 4	<b>authentication mode eigrp</b> <i>as-num</i> <b>md5</b>  <b>Example:</b> hostname(config)# <b>authentication mode eigrp</b> 2 <b>md5</b>	Enables MD5 authentication of EIGRP packets.  The <i>as-num</i> argument is the autonomous system number of the EIGRP routing process configured on the adaptive security appliance. If EIGRP is not enabled or if you enter the wrong number, the adaptive security appliance returns the following error message:  % Asystem(100) specified does not exist
Step 5	<b>authentication key eigrp</b> <i>as-num</i> <b>key</b> <i>key-id</i> <i>key-id</i>  <b>Example:</b> hostname(config)# <b>authentication key eigrp</b> 2 <b>cisco</b> <b>key-id</b> 200	Configures the key used by the MD5 algorithm.  The <i>as-num</i> argument is the autonomous system number of the EIGRP routing process configured on the adaptive security appliance. If EIGRP is not enabled or if you enter the wrong number, the adaptive security appliance returns the following error message:  % Asystem(100) specified does not exist  The <i>key</i> argument can include up to 16 characters.  The <i>key-id</i> argument is a number from 0 to 255.

## Defining an EIGRP Neighbor

EIGRP hello packets are sent as multicast packets. If an EIGRP neighbor is located across a non broadcast network, such as a tunnel, you must manually define that neighbor. When you manually define an EIGRP neighbor, hello packets are sent to that neighbor as unicast messages.

To manually define an EIGRP neighbor, perform the following steps:

### Detailed Steps

	Command	Purpose
Step 1	<b>router eigrp</b> <i>as-num</i>	Creates an EIGRP routing process and enters router configuration mode for this EIGRP process.
	<b>Example:</b> hostname(config)# <b>router eigrp</b> 2	The <i>as-num</i> argument is the autonomous system number of the EIGRP routing process.
Step 2	<b>neighbor</b> <i>ip-addr</i> <b>interface</b> <i>if_name</i>	Defines the static neighbor.
	<b>Example:</b> hostname(config)# <b>router eigrp</b> 2 hostname(config-router)# <b>neighbor</b> 10.0.0.0 <b>interface</b> <i>interface1</i>	The <i>ip-addr</i> argument is the IP address of the neighbor. The <i>if_name</i> argument is the name of the interface, as specified by the <b>nameif</b> command, through which that neighbor is available. You can define multiple neighbors for an EIGRP routing process.

## Redistributing Routes Into EIGRP

You can redistribute routes discovered by RIP and OSPF into the EIGRP routing process. You can also redistribute static and connected routes into the EIGRP routing process. You do not need to redistribute connected routes if they fall within the range of a **network** statement in the EIGRP configuration.

### Note

For RIP only: Before you begin this procedure, you must create a route-map to further define which routes from the specified routing protocol are redistributed in to the RIP routing process. See [Chapter 21, “Defining Route Maps,”](#) for more information about creating a route map.

To redistribute routes into the EIGRP routing process, perform the following steps:

## Detailed Steps

	Command	Purpose
Step 1	<b>router eigrp</b> <i>as-num</i>  <b>Example:</b> hostname(config)# <b>router eigrp</b> 2	Creates an EIGRP routing process and enters router configuration mode for this EIGRP process.  The <i>as-num</i> argument is the autonomous system number of the EIGRP routing process.
Step 2	<b>default-metric</b> <i>bandwidth delay reliability loading mtu</i>  <b>Example:</b> hostname(config)# <b>router eigrp</b> 2 hostname(config-router)# <b>default-metric</b> <i>bandwidth delay reliability loading mtu</i>	(Optional) Specifies the default metrics that should be applied to routes redistributed into the EIGRP routing process.  If you do not specify a default metric in the EIGRP router configuration, you must specify the metric values in each <b>redistribute</b> command. If you specify the EIGRP metrics in the <b>redistribute</b> command and have the <b>default-metric</b> command in the EIGRP router configuration, the metrics in the <b>redistribute</b> command are used.
Step 3	Do one of the following to redistribute the selected route type into the EIGRP routing process. You must specify the EIGRP metric values in the <b>redistribute</b> command if you do not have a <b>default-metric</b> command in the EIGRP router configuration.	
	<b>redistribute connected</b> [ <b>metric</b> <i>bandwidth delay reliability loading mtu</i> ] [ <b>route-map</b> <i>map_name</i> ]  <b>Example:</b> hostname(config-router): <b>redistribute connected</b> [ <b>metric</b> <i>bandwidth delay reliability loading mtu</i> ] [ <b>route-map</b> <i>map_name</i> ]	Redistributes connected routes into the EIGRP routing process.
	<b>redistribute static</b> [ <b>metric</b> <i>bandwidth delay reliability loading mtu</i> ] [ <b>route-map</b> <i>map_name</i> ]  <b>Example:</b> hostname(config-router): <b>redistribute static</b> [ <b>metric</b> <i>bandwidth delay reliability loading mtu</i> ] [ <b>route-map</b> <i>map_name</i> ]	Redistributes static routes into the EIGRP routing process.

Command	Purpose
<b>redistribute ospf</b> <i>pid</i> [ <b>match</b> { <b>internal</b>   <b>external</b> [1   2]   <b>nssa-external</b> [1   2]}] [ <b>metric</b> <i>bandwidth delay reliability loading mtu</i> ] [ <b>route-map</b> <i>map_name</i> ]  <b>Example:</b> hostname(config-router): <b>redistribute ospf</b> <i>pid</i> [ <b>match</b> { <b>internal</b>   <b>external</b> [1   2]   <b>nssa-external</b> [1   2]}] [ <b>metric</b> <i>bandwidth delay reliability loading mtu</i> ] [ <b>route-map</b> <i>map_name</i> ]	Redistributes routes from an OSPF routing process into the EIGRP routing process.
<b>redistribute rip</b> [ <b>metric</b> <i>bandwidth delay reliability load mtu</i> ] [ <b>route-map</b> <i>map_name</i> ]  <b>Example:</b> (config-router): <b>redistribute rip</b> [ <b>metric</b> <i>bandwidth delay reliability load mtu</i> ] [ <b>route-map</b> <i>map_name</i> ]	Redistributes routes from a RIP routing process into the EIGRP routing process.

## Filtering Networks in EIGRP

### Note

Before you begin this process, you must create a standard access list that defines the routes that you want to advertise. That is, create a standard access list that defines the routes that you want to filter from sending or receiving updates.

To filter networks in EIGRP, perform the following steps:

### Detailed Steps

	Command	Purpose
<b>Step 1</b>	<b>router eigrp</b> <i>as-num</i>  <b>Example:</b> hostname(config)# router eigrp 2	Creates an EIGRP routing process and enters router configuration mode for this EIGRP process.  The <i>as-num</i> argument is the autonomous system number of the EIGRP routing process.
<b>Step 2</b>	hostname(config-router)# <b>network</b> <i>ip-addr</i> [ <i>mask</i> ]  <b>Example:</b> hostname(config)# router eigrp 2 hostname(config-router)# network 10.0.0.0 255.0.0.0	Configure the interfaces and networks that participate in EIGRP routing. You can configure one or more <b>network</b> statements with this command.  Directly-connected and static networks that fall within the defined network are advertised by the adaptive security appliance. Additionally, only interfaces with an IP address that fall within the defined network participate in the EIGRP routing process.  If you have an interface that you do not want to have participate in EIGRP routing, but that is attached to a network that you want advertised, see the <a href="#">“Configuring Interfaces for EIGRP” section on page 24-6</a> .

Command	Purpose
<b>Step 3</b> Do one of the following to filter networks sent or received in EIGRP routing updates. You can enter multiple <b>distribute-list</b> commands in your EIGRP router configuration.	
<pre><b>distribute-list</b> <i>acl</i> <i>out</i> [<b>connected</b>   <b>ospf</b>   <b>rip</b>   <b>static</b>   <b>interface</b> <i>if_name</i>]</pre> <p><b>Example:</b></p> <pre>hostname(config)# router eigrp 2 hostname(config-router)# network 10.0.0.0 255.0.0.0 hostname(config-router): distribute-list acl out [connected]</pre>	<p>Allows you to filter networks sent in EIGRP routing updates.</p> <p>You can specify an interface to apply the filter to only those updates that are sent by that specific interface.</p>
<pre><b>distribute-list</b> <i>acl</i> <b>in</b> [<b>interface</b> <i>if_name</i>]</pre> <p><b>Example:</b></p> <pre>hostname(config)# router eigrp 2 hostname(config-router)# network 10.0.0.0 255.0.0.0 hostname(config-router): distribute-list acl in [interface interface1]</pre>	<p>Allows you to filter networks received in EIGRP routing updates.</p> <p>You can specify an interface to apply the filter to only those updates that are received by that interface.</p>

## Customizing the EIGRP Hello Interval and Hold Time

The adaptive security appliance periodically sends hello packets to discover neighbors and to learn when neighbors become unreachable or inoperative. By default, hello packets are sent every 5 seconds.

The hello packet advertises the adaptive security appliance hold time. The hold time indicates to EIGRP neighbors the length of time the neighbor should consider the adaptive security appliance reachable. If the neighbor does not receive a hello packet within the advertised hold time, then the adaptive security appliance is considered unreachable. By default, the advertised hold time is 15 seconds (three times the hello interval).

Both the hello interval and the advertised hold time are configured on a per-interface basis. We recommend setting the hold time to be at minimum three times the hello interval.

To configure the hello interval and advertised hold time, perform the following steps:

### Detailed Steps

Command	Purpose
<b>Step 1</b> <pre><b>interface</b> <i>phy_if</i></pre> <p><b>Example:</b></p> <pre>hostname(config)# interface <i>phy_if</i></pre>	<p>Enters interface configuration mode for the interface on which you are configuring the hello interval or advertised hold time.</p>

	Command	Purpose
Step 2	<b>hello-interval eigrp</b> <i>as-num seconds</i>  <b>Example:</b> hostname(config)# hello-interval eigrp 2 60	Allows you to change the hello interval.
Step 3	<b>hold-time eigrp</b> <i>as-num seconds</i>  <b>Example:</b> hostname(config)# hold-time eigrp 2 60	Allows you to change the hold time.

## Disabling Automatic Route Summarization

Automatic route summarization is enabled by default. The EIGRP routing process summarizes on network number boundaries. This can cause routing problems if you have noncontiguous networks.

For example, if you have a router with the networks 192.168.1.0, 192.168.2.0, and 192.168.3.0 connected to it, and those networks all participate in EIGRP, the EIGRP routing process creates the summary address 192.168.0.0 for those routes. If an additional router is added to the network with the networks 192.168.10.0 and 192.168.11.0, and those networks participate in EIGRP, they will also be summarized as 192.168.0.0. To prevent the possibility of traffic being routed to the wrong location, you should disable automatic route summarization on the routers creating the conflicting summary addresses.

To disable automatic router summarization, enter the following commands in router configuration mode for the EIGRP routing process:

### Detailed Steps

	Command	Purpose
Step 1	<b>router eigrp</b> <i>as-num</i>  <b>Example:</b> hostname(config)# router eigrp 2	Creates an EIGRP routing process and enters router configuration mode for this EIGRP process.  The <i>as-num</i> argument is the autonomous system number of the EIGRP routing process.
Step 2	<b>no auto-summary</b>  <b>Example:</b> hostname(config-router)# no auto-summary	Automatic summary addresses have an administrative distance of 5. You cannot configure this value.

## Configuring Default Information in EIGRP

You can control the sending and receiving of default route information in EIGRP updates. By default, default routes are sent and accepted. Configuring the adaptive security appliance to disallow default information to be received causes the candidate default route bit to be blocked on received routes. Configuring the adaptive security appliance to disallow default information to be sent disables the setting of the default route bit in advertised routes.

To configure default routing information, perform the following steps:

## Detailed Steps

	Command	Purpose
Step 1	<b>router eigrp</b> <i>as-num</i>	Creates an EIGRP routing process and enters router configuration mode for this EIGRP process.
	<b>Example:</b> hostname(config)# router eigrp 2	The <i>as-num</i> argument is the autonomous system number of the EIGRP routing process.
Step 2	hostname(config-router)# <b>network</b> <i>ip-addr</i> [ <i>mask</i> ]	Configures the interfaces and networks that participate in EIGRP routing. You can configure one or more <b>network</b> statements with this command.
	<b>Example:</b> hostname(config)# router eigrp 2 hostname(config-router)# network 10.0.0.0 255.0.0.0	Directly-connected and static networks that fall within the defined network are advertised by the adaptive security appliance. Additionally, only interfaces with an IP address that fall within the defined network participate in the EIGRP routing process.  If you have an interface that you do not want to have participate in EIGRP routing, but that is attached to a network that you want advertised, see the <a href="#">“Configuring Interfaces for EIGRP” section on page 24-6</a> .
Step 3	<b>no default-information</b> {in   out   WORD}	Allows you to control the sending or receiving of candidate default route information.
	<b>Example:</b> hostname(config)# router eigrp 2 hostname(config-router)# network 10.0.0.0 255.0.0.0 hostname(config-router)# no default-information {in   out   WORD}	Entering the <b>no default-information in</b> command causes the candidate default route bit to be blocked on received routes. Entering the <b>no default-information out</b> command disables the setting of the default route bit in advertised routes.

## Disabling EIGRP Split Horizon

Split horizon controls the sending of EIGRP update and query packets. When split horizon is enabled on an interface, update and query packets are not sent for destinations for which this interface is the next hop. Controlling update and query packets in this manner reduces the possibility of routing loops.

By default, split horizon is enabled on all interfaces.

Split horizon blocks route information from being advertised by a router out of any interface from which that information originated. This behavior usually optimizes communications among multiple routing devices, particularly when links are broken. However, with nonbroadcast networks, there may be situations where this behavior is not desired. For these situations, including networks in which you have EIGRP configured, you may want to disable split horizon.

If you disable split horizon on an interface, you must disable it for all routers and access servers on that interface.

To disable EIGRP split horizon, perform the following steps:

## Detailed Steps

	Command	Purpose
Step 1	<b>interface</b> <i>phy_if</i>  <b>Example:</b> hostname(config)# <b>interface</b> <i>phy_if</i>	Enters interface configuration mode for the interface on which you are changing the delay value used by EIGRP.
Step 2	<b>no split-horizon eigrp</b> <i>as-number</i>  <b>Example:</b> hostname(config-if)# <b>no split-horizon eigrp</b> <i>2</i>	Disables the split horizon.

## Restarting the EIGRP Process

To restart an EIGRP process or clear redistribution or counters, enter the following command:

```
hostname(config)# clear eigrp pid {1-65535 | neighbors | topology | events}}
```

## Monitoring EIGRP

You can use the following commands to monitor the EIGRP routing process. For examples and descriptions of the command output, see the *Cisco ASA 5500 Series Command Reference*. Additionally, you can disable the logging of neighbor change messages and neighbor warning messages.

To monitor or disable various EIGRP routing statistics, enter one of the following commands:

Command	Purpose
<b>Monitoring EIGRP Routing</b>	
<b>show eigrp</b> [ <i>as-number</i> ] <b>events</b> [{ <i>start end</i> }   <b>type</b> ]	Displays the EIGRP event log.
<b>show eigrp</b> [ <i>as-number</i> ] <b>neighbors</b> [ <b>detail</b>   <b>static</b> ] [ <i>if-name</i> ]	Displays the EIGRP neighbor table.
<b>show eigrp</b> [ <i>as-number</i> ] <b>interfaces</b> [ <i>if-name</i> ] [ <b>detail</b> ]	Displays the interfaces participating in EIGRP routing.
<b>show eigrp</b> [ <i>as-number</i> ] <b>topology</b> [ <i>ip-addr</i> [ <i>mask</i> ]   <b>active</b>   <b>all-links</b>   <b>pending</b>   <b>summary</b>   <b>zero-successors</b> ]	Displays the EIGRP topology table.
<b>show eigrp</b> [ <i>as-number</i> ] <b>traffic</b>	Displays EIGRP traffic statistics.
<b>router-id</b>	Displays the router-id for this EIGRP process.
<b>Disabling EIGRP Logging Messages</b>	

Command	Purpose
<code>no eigrp log-neighbor-changes</code>	Disables the logging of neighbor change messages. Enter this command in router configuration mode for the EIGRP routing process.
<code>no eigrp log-neighbor-warnings</code>	Disables the logging of neighbor warning messages.

**Note**

By default, neighbor change and neighbor warning messages are logged.

## Configuration Example for EIGRP

The following example shows how to enable and configure EIGRP with various optional processes:

- 
- Step 1** Enable EIGRP:
- ```
hostname(config)# router eigrp 2
hostname(config-router)# network 10.0.0.0 255.0.0.0
```
- Step 2** Configure an interface from sending or receiving EIGRP routing message:
- ```
hostname(config-router)# passive-interface {default}
```
- Step 3** Define an EIGRP neighbor:
- ```
hostname(config-router)# neighbor 10.0.0.0 interface interface1
```
- Step 4** Configure the interfaces and networks that participate in EIGRP routing:
- ```
hostname(config-router)# network 10.0.0.0 255.0.0.0
```
- Step 5** Change the interface delay value is used in EIGRP distance calculations:
- ```
hostname(config-router)# exit
hostname(config)# interface phy_if
hostname(config-if)# delay 200
```
-

# Feature History for EIGRP

Table 24-1 lists each feature change and the platform release in which it was implemented.

**Table 24-1** Feature History for EIGRP

| Feature Name  | Platform Releases | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                     |

# CHAPTER 25

## Configuring Multicast Routing

---

This chapter describes how to configure the adaptive security appliance to use the multicast routing protocol and includes the following sections:

- [Information About Multicast Routing, page 25-1](#)
- [Licensing Requirements for Multicast Routing, page 25-2](#)
- [Guidelines and Limitations, page 25-3](#)
- [Enabling Multicast Routing, page 25-3](#)
- [Customizing Multicast Routing, page 25-4](#)
- [Configuration Example for Multicast Routing, page 25-14](#)
- [Additional References, page 25-15](#)
- [Feature History for Multicast Routing, page 25-15](#)

## Information About Multicast Routing

Multicast routing is a bandwidth-conserving technology that reduces traffic by simultaneously delivering a single stream of information to thousands of corporate recipients and homes. Applications that take advantage of multicast routing include videoconferencing, corporate communications, distance learning, and distribution of software, stock quotes, and news.

Multicast routing protocols delivers source traffic to multiple receivers without adding any additional burden on the source or the receivers while using the least network bandwidth of any competing technology. Multicast packets are replicated in the network by Cisco routers enabled with Protocol Independent Multicast (PIM) and other supporting multicast protocols resulting in the most efficient delivery of data to multiple receivers possible.

The adaptive security appliance supports both stub multicast routing and PIM multicast routing. However, you cannot configure both concurrently on a single adaptive security appliance.

### Note

---

Only the UDP transport layer is supported for multicast routing.

---

## Stub Multicast Routing

Stub multicast routing provides dynamic host registration and facilitates multicast routing. When configured for stub multicast routing, the adaptive security appliance acts as an IGMP proxy agent. Instead of fully participating in multicast routing, the adaptive security appliance forwards IGMP messages to an upstream multicast router, which sets up delivery of the multicast data. When configured for stub multicast routing, the adaptive security appliance cannot be configured for PIM.

The adaptive security appliance supports both PIM-SM and bi-directional PIM. PIM-SM is a multicast routing protocol that uses the underlying unicast routing information base or a separate multicast-capable routing information base. It builds unidirectional shared trees rooted at a single Rendezvous Point per multicast group and optionally creates shortest-path trees per multicast source.

## PIM Multicast Routing

Bi-directional PIM is a variant of PIM-SM that builds bi-directional shared trees connecting multicast sources and receivers. Bi-directional trees are built using a DF election process operating on each link of the multicast topology. With the assistance of the DF, multicast data is forwarded from sources to the Rendezvous Point, and therefore along the shared tree to receivers, without requiring source-specific state. The DF election takes place during Rendezvous Point discovery and provides a default route to the Rendezvous Point.

**Note**

If the adaptive security appliance is the PIM RP, use the untranslated outside address of the adaptive security appliance as the RP address.

## Multicast Group Concept

Multicast is based on the concept of a group. An arbitrary group of receivers expresses an interest in receiving a particular data stream. This group does not have any physical or geographical boundaries—the hosts can be located anywhere on the Internet. Hosts that are interested in receiving data flowing to a particular group must join the group using IGMP. Hosts must be a member of the group to receive the data stream.

## Multicast Addresses

Multicast addresses specify an arbitrary group of IP hosts that have joined the group and want to receive traffic sent to this group.

## Licensing Requirements for Multicast Routing

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

# Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

## Context Mode Guidelines

Supported in single context mode. In multiple context mode, unshared interfaces and shared interfaces are not supported.

## Firewall Mode Guidelines

Supported only in routed mode. Transparent mode is not supported.

## IPv6 Guidelines

Does not support IPv6.

# Enabling Multicast Routing

Enabling multicast routing lets you enable multicast routing on the adaptive security appliance. Enabling multicast routing enables IGMP and PIM on all interfaces by default. IGMP is used to learn whether members of a group are present on directly attached subnets. Hosts join multicast groups by sending IGMP report messages. PIM is used to maintain forwarding tables to forward multicast datagrams.

### Note

Only the UDP transport layer is supported for multicast routing.

To enable multicast routing, enter the following command:

| Command                                                | Purpose                                                                                                                    |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>multicast-routing</b>                               | Enables multicast routing.                                                                                                 |
| <b>Example:</b><br>hostname(config)# multicast-routing | The number of entries in the multicast routing tables are limited by the amount of RAM on the adaptive security appliance. |

Table 25-1 lists the maximum number of entries for specific multicast tables based on the amount of RAM on the adaptive security appliance. Once these limits are reached, any new entries are discarded.

**Table 25-1 Entry Limits for Multicast Tables**

| Table              | 16 MB | 128 MB | 128+ MB |
|--------------------|-------|--------|---------|
| <b>MFIB</b>        | 1000  | 3000   | 5000    |
| <b>IGMP Groups</b> | 1000  | 3000   | 5000    |
| <b>PIM Routes</b>  | 3000  | 7000   | 12000   |

# Customizing Multicast Routing

This section describes how to customize multicast routing and includes the following topics:

- [Configuring Stub Multicast Routing, page 25-4](#)
- [Configuring a Static Multicast Route, page 25-4](#)
- [Configuring IGMP Features, page 25-5](#)
- [Configuring PIM Features, page 25-9](#)
- [Configuring a Bidirectional Neighbor Filter, page 25-13](#)
- [Configuring a Multicast Boundary, page 25-14](#)

## Configuring Stub Multicast Routing

**Note**

Stub multicast routing and PIM are not supported concurrently.

An adaptive security appliance acting as the gateway to the stub area does not need to participate in PIM. Instead, you can configure it to act as an IGMP proxy agent and forward IGMP messages from hosts connected on one interface to an upstream multicast router on another. To configure the adaptive security appliance as an IGMP proxy agent, forward the host join and leave messages from the stub area interface to an upstream interface.

To forward the host join and leave messages, enter the following command from the interface attached to the stub area:

| Command                                                                                           | Purpose                            |
|---------------------------------------------------------------------------------------------------|------------------------------------|
| <code>igmp forward interface <i>if_name</i></code>                                                | Configures stub multicast routing. |
| <b>Example:</b><br><code>hostname(config-if)# igmp forward<br/>interface <i>interface1</i></code> |                                    |

## Configuring a Static Multicast Route

Configuring static multicast routes lets you separate multicast traffic from unicast traffic. For example, when a path between a source and destination does not support multicast routing, the solution is to configure two multicast devices with a GRE tunnel between them and to send the multicast packets over the tunnel.

When using PIM, the adaptive security appliance expects to receive packets on the same interface where it sends unicast packets back to the source. In some cases, such as bypassing a route that does not support multicast routing, you may want unicast packets to take one path and multicast packets to take another.

Static multicast routes are not advertised or redistributed.

To configure a static multicast route or a static multicast route for a stub area, enter one of the following commands:

| Command                                                                                                                                                                                                        | Purpose                                                                                                                                                             |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mroute</b> <i>src_ip src_mask {input_if_name   rpf_neighbor} [distance]</i><br><br><b>Example:</b><br>hostname(config)# mroute <i>src_ip src_mask {input_if_name   rpf_neighbor} [distance]</i>             | Configures a static multicast route.                                                                                                                                |
| <b>mroute</b> <i>src_ip src_mask input_if_name [dense output_if_name] [distance]</i><br><br><b>Example:</b><br>hostname(config)# mroute <i>src_ip src_mask input_if_name [dense output_if_name] [distance]</i> | Configures a static multicast route for a stub area.<br><br>The <b>dense output_if_name</b> keyword and argument pair is only supported for stub multicast routing. |

## Configuring IGMP Features

IP hosts use Internet Group Management Protocol, or IGMP, to report their group memberships to directly connected multicast routers.

IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

IGMP uses group addresses (Class D IP address) as group identifiers. Host group address can be in the range 224.0.0.0 to 239.255.255.255. The address 224.0.0.0 is never assigned to any group. The address 224.0.0.1 is assigned to all systems on a subnet. The address 224.0.0.2 is assigned to all routers on a subnet.

When you enable multicast routing on the adaptive security appliance, IGMP Version 2 is automatically enabled on all interfaces.

### Note

Only the **no igmp** command appears in the interface configuration when you use the **show run** command. If the **multicast-routing** command appears in the device configuration, then IGMP is automatically enabled on all interfaces.

This section describes how to configure optional IGMP setting on a per-interface basis and includes the following topics:

- [Disabling IGMP on an Interface, page 25-6](#)
- [Configuring IGMP Group Membership, page 25-6](#)
- [Configuring a Statically Joined IGMP Group, page 25-6](#)
- [Controlling Access to Multicast Groups, page 25-7](#)
- [Limiting the Number of IGMP States on an Interface, page 25-7](#)
- [Modifying the Query Messages to Multicast Groups, page 25-8](#)

- [Changing the IGMP Version, page 25-9](#)

## Disabling IGMP on an Interface

You can disable IGMP on specific interfaces. This is useful if you know that you do not have any multicast hosts on a specific interface and you want to prevent the adaptive security appliance from sending host query messages on that interface.

To disable IGMP on an interface, enter the following command:

| Command                                                      | Purpose                                                                                              |
|--------------------------------------------------------------|------------------------------------------------------------------------------------------------------|
| <code>no igmp</code>                                         | Disables IGMP on an interface.<br><br>To reenable IGMP on an interface, use the <b>igmp</b> command. |
| <b>Example:</b><br><code>hostname(config-if)# no igmp</code> |                                                                                                      |

**Note**

Only the **no igmp** command appears in the interface configuration.

## Configuring IGMP Group Membership

You can configure the adaptive security appliance to be a member of a multicast group. Configuring the adaptive security appliance to join a multicast group causes upstream routers to maintain multicast routing table information for that group and keep the paths for that group active.

**Note**

If you want to forward multicast packets for a specific group to an interface without the adaptive security appliance accepting those packets as part of the group, see the [“Configuring a Statically Joined IGMP Group” section on page 25-6](#).

To have the adaptive security appliance join a multicast group, enter the following command:

| Command                                                                              | Purpose                                                                         |
|--------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| <code>igmp join-group group-address</code>                                           | Configures the adaptive security appliance to be a member of a multicast group. |
| <b>Example:</b><br><code>hostname(config-if)# igmp join-group<br/>mcast-group</code> | The <i>group-address</i> is the IP address of the group.                        |

## Configuring a Statically Joined IGMP Group

Sometimes a group member cannot report its membership in the group because of some configuration, or there may be no members of a group on the network segment. However, you still want multicast traffic for that group to be sent to that network segment. You can have multicast traffic for that group sent to the segment by configuring a statically joined IGMP group.

From the command line, use the **igmp static-group** command. The adaptive security appliance does not accept the multicast packets but rather forwards them to the specified interface.

To configure a statically joined multicast group on an interface, enter the following command

| Command                                                                                  | Purpose                                                                                       |
|------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| <b>igmp static-group</b>                                                                 | Configures the adaptive security appliance statically join a multicast group on an interface. |
| <b>Example:</b><br>hostname(config-if)# <b>igmp static-group</b><br><i>group-address</i> | The <i>group-address</i> is the IP address of the group.                                      |

## Controlling Access to Multicast Groups

To control the multicast groups that hosts on the adaptive security appliance interface can join, perform the following steps:

### Detailed Steps

|               | Command                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                  |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Do one of the following to create a standard or extended access list.                                                                                 |                                                                                                                                                                                                                                                                                          |
|               | <b>access-list</b> <i>name</i> <b>standard</b> [ <b>permit</b>   <b>deny</b> ]<br><i>ip_addr mask</i>                                                 | Creates a standard access list for the multicast traffic.<br><br>You can create more than one entry for a single access list. You can use extended or standard access lists.<br><br>The <i>ip_addr mask</i> argument is the IP address of the multicast group being permitted or denied. |
|               | <b>Example:</b><br>hostname(config)# access-list <i>acl1</i><br>standard permit <i>192.52.662.25</i>                                                  |                                                                                                                                                                                                                                                                                          |
|               | <b>access-list</b> <i>name</i> <b>extended</b> [ <b>permit</b>   <b>deny</b> ]<br><i>protocol src_ip_addr src_mask dst_ip_addr</i><br><i>dst_mask</i> | Creates an extended access list.<br><br>The <i>dst_ip_addr</i> argument is the IP address of the multicast group being permitted or denied.                                                                                                                                              |
|               | <b>Example:</b><br>hostname(config)# access-list <i>acl2</i><br>extended permit <i>protocol src_ip_addr</i><br><i>src_mask dst_ip_addr dst_mask</i>   |                                                                                                                                                                                                                                                                                          |
| <b>Step 2</b> | <b>igmp access-group</b> <i>acl</i>                                                                                                                   | Applies the access list to an interface.<br><br>The <i>acl</i> argument is the name of a standard or extended IP access list.                                                                                                                                                            |
|               | <b>Example:</b><br>hostname(config-if)# <b>igmp access-group</b> <i>acl</i>                                                                           |                                                                                                                                                                                                                                                                                          |

## Limiting the Number of IGMP States on an Interface

You can limit the number of IGMP states resulting from IGMP membership reports on a per-interface basis. Membership reports exceeding the configured limits are not entered in the IGMP cache and traffic for the excess membership reports is not forwarded.

To limit the number of IGMP states on an interface, enter the following command:

| Command                                               | Purpose                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>igmp limit</b> <i>number</i>                       | Limits the number of IGMP states on an interface.                                                                                                                                                                                                                                                                                   |
| <b>Example:</b><br>hostname(config-if)# igmp limit 50 | Valid values range from 0 to 500, with 500 being the default value. Setting this value to 0 prevents learned groups from being added, but manually defined memberships (using the <b>igmp join-group</b> and <b>igmp static-group</b> commands) are still permitted. The <b>no</b> form of this command restores the default value. |

## Modifying the Query Messages to Multicast Groups

### Note

The **igmp query-timeout** and **igmp query-interval** commands require IGMP Version 2.

The adaptive security appliance sends query messages to discover which multicast groups have members on the networks attached to the interfaces. Members respond with IGMP report messages indicating that they want to receive multicast packets for specific groups. Query messages are addressed to the all-systems multicast group, which has an address of 224.0.0.1, with a time-to-live value of 1.

These messages are sent periodically to refresh the membership information stored on the adaptive security appliance. If the adaptive security appliance discovers that there are no local members of a multicast group still attached to an interface, it stops forwarding multicast packet for that group to the attached network and it sends a prune message back to the source of the packets.

By default, the PIM designated router on the subnet is responsible for sending the query messages. By default, they are sent once every 125 seconds.

When changing the query response time, by default, the maximum query response time advertised in IGMP queries is 10 seconds. If the adaptive security appliance does not receive a response to a host query within this amount of time, it deletes the group.

To change the query interval, query response time, and query timeout value, perform the following steps:

### Detailed Steps

|               | Command                                                        | Purpose                                                                                                                                                                                                                                                                                                                  |
|---------------|----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>igmp query-interval</b> <i>seconds</i>                      | Sets the query interval time in seconds.                                                                                                                                                                                                                                                                                 |
|               | <b>Example:</b><br>hostname(config-if)# igmp query-interval 30 | Valid values range from 0 to 500; 125 is the default value.<br><br>If the adaptive security appliance does not hear a query message on an interface for the specified timeout value (by default, 255 seconds), then the adaptive security appliance becomes the designated router and starts sending the query messages. |

|        | Command                                                                                                                                       | Purpose                                                                                                            |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 2 | <code>igmp query-timeout seconds</code><br><br><b>Example:</b><br><code>hostname(config-if)# igmp query-timeout 30</code>                     | Changes the timeout value of the query.<br><br>Valid values range from 0 to 500, with 225 being the default value. |
| Step 3 | <code>igmp query-max-response-time seconds</code><br><br><b>Example:</b><br><code>hostname(config-if)# igmp query-max-response-time 30</code> | Changes the maximum query response time.                                                                           |

## Changing the IGMP Version

By default, the adaptive security appliance runs IGMP Version 2, which enables several additional features such as the `igmp query-timeout` and `igmp query-interval` commands.

All multicast routers on a subnet must support the same version of IGMP. The adaptive security appliance does not automatically detect version 1 routers and switch to version 1. However, a mix of IGMP Version 1 and 2 hosts on the subnet works; the adaptive security appliance running IGMP Version 2 works correctly when IGMP Version 1 hosts are present.

To control which version of IGMP is running on an interface, enter the following command:

| Command                                                                                                      | Purpose                                                               |
|--------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| <code>igmp version {1   2}</code><br><br><b>Example:</b><br><code>hostname(config-if)# igmp version 2</code> | Controls which version of IGMP that you want to run on the interface. |

## Configuring PIM Features

Routers use PIM to maintain forwarding tables for forwarding multicast diagrams. When you enable multicast routing on the adaptive security appliance, PIM and IGMP are automatically enabled on all interfaces.

### Note

PIM is not supported with PAT. The PIM protocol does not use ports and PAT only works with protocols that use ports.

This section describes how to configure optional PIM settings and includes the following topics:

- [Enabling and Disabling PIM on an Interface, page 25-10](#)
- [Configuring a Static Rendezvous Point Address, page 25-10](#)
- [Configuring the Designated Router Priority, page 25-11](#)
- [Configuring and Filtering PIM Register Messages, page 25-11](#)
- [Configuring PIM Message Intervals, page 25-12](#)
- [Filtering PIM Neighbors, page 25-12](#)

## Enabling and Disabling PIM on an Interface

You can enable or disable PIM on specific interfaces. To enable or disable PIM on an interface, perform the following steps:

### Detailed Steps

|        | Command                                                             | Purpose                                           |
|--------|---------------------------------------------------------------------|---------------------------------------------------|
| Step 1 | <b>pim</b><br><br><b>Example:</b><br>hostname(config-if)# pim       | Enables or reenables PIM on a specific interface. |
| Step 2 | <b>no pim</b><br><br><b>Example:</b><br>hostname(config-if)# no pim | Disables PIM on a specific interface.             |

#### Note

Only the **no pim** command appears in the interface configuration.

## Configuring a Static Rendezvous Point Address

All routers within a common PIM sparse mode or bidir domain require knowledge of the PIM RP address. The address is statically configured using the **pim rp-address** command.

#### Note

The adaptive security appliance does not support Auto-RP or PIM BSR. You must use the **pim rp-address** command to specify the RP address.

You can configure the adaptive security appliance to serve as RP to more than one group. The group range specified in the access list determines the PIM RP group mapping. If an access list is not specified, then the RP for the group is applied to the entire multicast group range (224.0.0.0/4).

To configure the address of the PIM PR, enter the following command:

| Command                                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>pim rp-address</b> <i>ip_address</i> [ <i>acl</i> ] [ <b>bidir</b> ]<br><br><b>Example:</b><br>hostname(config)# pim rp-address<br>10.86.75.23 [acl11] [bidir] | Enables or reenables PIM on a specific interface.<br><br>The <i>ip_address</i> argument is the unicast IP address of the router to be a PIM RP.<br><br>The <i>acl</i> argument is the name or number of a standard access list that defines which multicast groups the RP should be used with. Do not use a host ACL with this command.<br><br>Excluding the <b>bidir</b> keyword causes the groups to operate in PIM sparse mode. |

**Note**

The adaptive security appliance always advertises the bidirectional capability in the PIM hello messages regardless of the actual bidirectional configuration.

## Configuring the Designated Router Priority

The DR is responsible for sending PIM register, join, and prune messages to the RP. When there is more than one multicast router on a network segment, there is an election process to select the DR based on DR priority. If multiple devices have the same DR priority, then the device with the highest IP address becomes the DR.

By default, the adaptive security appliance has a DR priority of 1. To change this value, enter the following command:

| Command                                                     | Purpose                                                                                                    |
|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| <b>pim dr-priority</b> <i>num</i>                           | Changes the designated router priority.<br>The <i>num</i> argument can be any number from 1 to 4294967294. |
| <b>Example:</b><br>hostname(config-if)# pim dr-priority 500 |                                                                                                            |

## Configuring and Filtering PIM Register Messages

When the adaptive security appliance is acting as an RP, you can restrict specific multicast sources from registering with it. This prevents unauthorized sources from registering with the RP. The Request Filter pane lets you define the multicast sources from which the adaptive security appliance will accept PIM register messages.

To filter PIM register messages, enter the following command:

| Command                                                                                                 | Purpose                                                                                                                                                                                               |
|---------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>pim accept-register</b> { <i>list acl</i>   <i>route-map map-name</i> }                              | Configures the adaptive security appliance to filter PIM register messages.<br>In this example, the adaptive security appliance filters PIM register messages <i>acl1</i> and route map <i>map2</i> . |
| <b>Example:</b><br>hostname(config)# pim accept-register<br>{list <i>acl1</i>   route-map <i>map2</i> } |                                                                                                                                                                                                       |

## Configuring PIM Message Intervals

Router query messages are used to select the PIM DR. The PIM DR is responsible for sending router query messages. By default, router query messages are sent every 30 seconds. Additionally, every 60 seconds, the adaptive security appliance sends PIM join/prune messages.

To change these intervals, perform the following steps:

### Detailed Steps

|        | Command                                                                                                                 | Purpose                                                                                                                                                                                       |
|--------|-------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>pim hello-interval</b> <i>seconds</i><br><br><b>Example:</b><br>hostname(config-if)# pim hello-interval 60           | Sends router query messages.<br><br>Valid values for the <i>seconds</i> argument range from 1 to 3600 seconds.                                                                                |
| Step 2 | <b>pim join-prune-interval</b> <i>seconds</i><br><br><b>Example:</b><br>hostname(config-if)# pim join-prune-interval 60 | Changes the amount of time (in seconds) that the adaptive security appliance sends PIM join/prune messages.<br><br>Valid values for the <i>seconds</i> argument range from 10 to 600 seconds. |

## Filtering PIM Neighbors

You can define the routers that can become PIM neighbors. By filtering the routers that can become PIM neighbors, you can do the following:

- Prevent unauthorized routers from becoming PIM neighbors.
- Prevent attached stub routers from participating in PIM.

To define the neighbors that can become a PIM neighbor, perform the following steps:

### Detailed Steps

|        | Command                                                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                          |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>access-list</b> <b>pim_nbr</b> <b>deny</b> <i>router-IP_addr</i><br><i>PIM neighbor</i><br><br><b>Example:</b><br>hostname(config)# access-list pim_nbr deny 10.1.1.1 255.255.255.255 | Uses a standard access list to define the routers that you want to have participate in PIM.<br><br>In this example, the following access list, when used with the <b>pim neighbor-filter</b> command, prevents the 10.1.1.1 router from becoming a PIM neighbor: |
| Step 2 | <b>pim neighbor-filter</b> <b>pim_nbr</b><br><br><b>Example:</b><br>hostname(config)# interface GigabitEthernet0/3<br>hostname(config-if)# pim neighbor-filter pim_nbr                   | Filters neighbor routers.<br><br>In this example, the 10.1.1.1 router is prevented from becoming a PIM neighbor on interface GigabitEthernet0/3.                                                                                                                 |

## Configuring a Bidirectional Neighbor Filter

The Bidirectional Neighbor Filter pane shows the PIM bidirectional neighbor filters, if any, that are configured on the adaptive security appliance. A PIM bidirectional neighbor filter is an ACL that defines the neighbor devices that can participate in the DF election. If a PIM bidirectional neighbor filter is not configured for an interface, then there are no restrictions. If a PIM bidirectional neighbor filter is configured, only those neighbors permitted by the ACL can participate in DF election process.

When a PIM bidirectional neighbor filter configuration is applied to the adaptive security appliance, an ACL appears in the running configuration with the name *interface-name\_multicast*, to which the *interface-name* is the name of the interface the multicast boundary filter is applied. If an ACL with that name already exists, a number is appended to the name, for example *inside\_multicast\_1*. This ACL defines which devices can become PIM neighbors of the adaptive security appliance.

Bidirectional PIM allows multicast routers to keep reduced state information. All of the multicast routers in a segment must be bidirectionally enabled for bidir to elect a DF.

The PIM bidirectional neighbor filters enable the transition from a sparse-mode-only network to a bidir network by letting you specify the routers that should participate in DF election while still allowing all routers to participate in the sparse-mode domain. The bidir-enabled routers can elect a DF from among themselves, even when there are non-bidir routers on the segment. Multicast boundaries on the non-bidir routers prevent PIM messages and data from the bidir groups from leaking in or out of the bidir subset cloud.

When a PIM bidirectional neighbor filter is enabled, the routers that are permitted by the ACL are considered to be bidirectionally capable. Therefore:

- If a permitted neighbor does not support bidir, the DF election does not occur.
- If a denied neighbor supports bidir, then DF election does not occur.
- If a denied neighbor does not support bidir, the DF election can occur.

To define the neighbors that can become a PIM bidirectional neighbor filter, perform the following steps:

### Detailed Steps

|        | Command                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                          |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>access-list pim_nbr deny router-IP_addr PIM neighbor</b><br><br><b>Example:</b><br>hostname(config)# access-list pim_nbr deny 10.1.1.1 255.255.255.255                                   | Uses a standard access list to define the routers that you want to have participate in PIM.<br><br>In this example, the following access list, when used with the <b>pim neighbor-filter</b> command, prevents the 10.1.1.1 router from becoming a PIM neighbor. |
| Step 2 | <b>pim bidirectional-neighbor-filter pim_nbr</b><br><br><b>Example:</b><br>hostname(config)# interface GigabitEthernet0/3<br>hostname(config-if)# pim bidirectional neighbor-filter pim_nbr | Filters neighbor routers.<br><br>In this example, the 10.1.1.1 router is prevented from becoming a PIM bidirectional neighbor on interface GigabitEthernet0/3.                                                                                                   |

The PIM Bidirectional Neighbor Filter table contains the following entries. Double-click an entry to open the Edit Bidirectional Neighbor Filter Entry dialog box for that entry.

The Add/Edit/Insert Bidirectional Neighbor Filter Entry dialog box lets you create ACL entries for the PIM bidirectional neighbor filter ACL.

Select the interface for which you are configuring the PIM bidirectional neighbor filter ACL entry. Choose **Permit** to allow the specified devices to participate in the DF election process. Choose **Deny** to prevent the specified devices from participating in the DF election process.

## Configuring a Multicast Boundary

Address scoping defines domain boundaries so that domains with RPs that have the same IP address do not leak into each other. Scoping is performed on the subnet boundaries within large domains and on the boundaries between the domain and the Internet.

You can set up an administratively scoped boundary on an interface for multicast group addresses using the **multicast boundary** command. IANA has designated the multicast address range 239.0.0.0 to 239.255.255.255 as the administratively scoped addresses. This range of addresses can be reused in domains administered by different organizations. They would be considered local, not globally unique.

A standard ACL defines the range of addresses affected. When a boundary is set up, no multicast data packets are allowed to flow across the boundary from either direction. The boundary allows the same multicast group address to be reused in different administrative domains.

You can configure the **filter-autorp** keyword to examine, and filter Auto-RP discovery and announcement messages at the administratively scoped boundary. Any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary access control list (ACL) are removed. An Auto-RP group range announcement is permitted and passed by the boundary only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

To configure a multicast boundary, enter the following command:

| Command                                                                                    | Purpose                          |
|--------------------------------------------------------------------------------------------|----------------------------------|
| <b>multicast boundary</b> <i>acl</i> [ <b>filter-autorp</b> ]                              | Configures a multicast boundary. |
| <b>Example:</b><br><pre>hostname(config-if)# multicast boundary acl1 [filter-autorp]</pre> |                                  |

## Configuration Example for Multicast Routing

The following example shows how to enable and configure multicast routing with various optional processes:

### Step 1 Enable multicast routing:

```
hostname(config)# multicast-routing
```

### Step 2 Configure a static multicast route:

```
hostname(config)# mroute src_ip src_mask {input_if_name | rpf_neighbor} [distance]
hostname(config)# exit
```

**Step 3** Configure the configure the adaptive security appliance to be a member of a multicast group:

```
hostname(config) # interface
hostname(config-if)# igmp join-group group-address
```

# CHAPTER 26

## Configuring IPv6 Neighbor Discovery

---

The IPv6 neighbor discovery process uses ICMPv6 messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), verify the readability of a neighbor, and keep track of neighboring routers. For information about how to configure IPv6 Neighbor Discovery in ASDM, see the *Cisco ASA 5500 Series Configuration Guide using ASDM*.

This chapter describes how to enable and configure IPv6 neighbor discovery on the adaptive security appliance and includes the following sections:

- [Configuring Neighbor Solicitation Messages, page 26-1](#)
- [Configuring Router Advertisement Messages, page 26-7](#)
- [Configuring a Static IPv6 Neighbor, page 26-19](#)

## Configuring Neighbor Solicitation Messages

This section includes the following topics:

- [Configuring the Neighbor Solicitation Message Interval, page 26-1](#)
- [Configuring the Neighbor Reachable Time, page 26-4](#)

## Configuring the Neighbor Solicitation Message Interval

- [Information About Neighbor Solicitation Messages, page 26-2](#)
- [Licensing Requirements for Neighbor Solicitation Messages, page 26-2](#)
- [Guidelines and Limitations for the Neighbor Solicitation Message Interval, page 26-3](#)
- [Default Settings for the Neighbor Solicitation Message Interval, page 26-3](#)
- [Configuring the Neighbor Solicitation Message Interval, page 26-3](#)
- [Monitoring Neighbor Solicitation Message Intervals, page 26-4](#)
- [Feature History for the Neighbor Solicitation Message Interval, page 26-4](#)

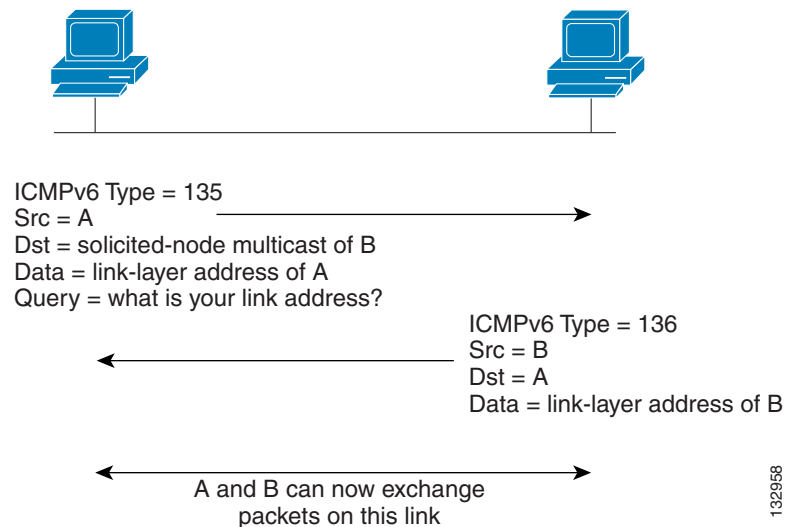

## Information About Neighbor Solicitation Messages

Neighbor solicitation messages (ICMPv6 Type 135) are sent on the local link by nodes attempting to discover the link-layer addresses of other nodes on the local link. The neighbor solicitation message is sent to the solicited-node multicast address. The source address in the neighbor solicitation message is the IPv6 address of the node sending the neighbor solicitation message. The neighbor solicitation message also includes the link-layer address of the source node.

After receiving a neighbor solicitation message, the destination node replies by sending a neighbor advertisement message (ICMPv6 Type 136) on the local link. The source address in the neighbor advertisement message is the IPv6 address of the node sending the neighbor advertisement message; the destination address is the IPv6 address of the node that sent the neighbor solicitation message. The data portion of the neighbor advertisement message includes the link-layer address of the node sending the neighbor advertisement message.

After the source node receives the neighbor advertisement, the source node and destination node can communicate. [Figure 26-1](#) shows the neighbor solicitation and response process.

**Figure 26-1 IPv6 Neighbor Discovery—Neighbor Solicitation Message**

Neighbor solicitation messages are also used to verify the reachability of a neighbor after the link-layer address of a neighbor is identified. When a node wants to verify the reachability of a neighbor, the destination address in a neighbor solicitation message is the unicast address of the neighbor.

Neighbor advertisement messages are also sent when there is a change in the link-layer address of a node on a local link. When there is such a change, the destination address for the neighbor advertisement is the all-nodes multicast address.

## Licensing Requirements for Neighbor Solicitation Messages

The following table shows the licensing requirements for this feature:

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Guidelines and Limitations for the Neighbor Solicitation Message Interval

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported in routed mode only. Transparent mode is not supported.

### Additional Guidelines and Limitations

The interval value is included in all IPv6 router advertisements sent out this interface.

## Default Settings for the Neighbor Solicitation Message Interval

Table 26-1 lists the default settings for neighbor solicitation message parameters.

**Table 26-1** Default Neighbor Solicitation Messages Parameters

| Parameters                           | Default                                                  |
|--------------------------------------|----------------------------------------------------------|
| <i>value</i> (transmission interval) | 1000 seconds between neighbor solicitation transmissions |

## Configuring the Neighbor Solicitation Message Interval

To configure the interval between IPv6 neighbor solicitation retransmissions on an interface, enter the following command:

| Command                                                                        | Purpose                                                                                                                                             |
|--------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ipv6 nd ns-interval value</code>                                         | Sets the interval between IPv6 neighbor solicitation retransmissions on an interface.                                                               |
| <b>Example:</b><br><code>hostname (config-if)# ipv6 nd ns-interval 9000</code> | Valid values for the value argument range from 1000 to 3600000 milliseconds.<br><br>This information is also sent in router advertisement messages. |

### Examples

The following example configures an IPv6 neighbor solicitation transmission interval of 9000 milliseconds for GigabitEthernet 0/0:

```
hostname (config)# interface gigabitethernet 0/0
hostname (config-if)# ipv6 nd ns-interval 9000
```

## Monitoring Neighbor Solicitation Message Intervals

To monitor IPv6 neighbor solicitation message intervals, enter the following command:

| Command                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>show ipv6 interface</code> | <p>Displays the usability status of interfaces configured for IPv6. Including the interface name, such as “outside,” displays the settings for the specified interface. Excluding the name from the command displays the settings for all interfaces that have IPv6 enabled on them. Output for the command shows the following:</p> <ul style="list-style-type: none"> <li>• The name and status of the interface.</li> <li>• The link-local and global unicast addresses.</li> <li>• The multicast groups to which the interface belongs.</li> <li>• ICMP redirect and error message settings.</li> <li>• Neighbor discovery settings.</li> <li>• The actual time when the command is set to 0.</li> <li>• The neighbor discovery reachable time that is being used.</li> </ul> |

## Feature History for the Neighbor Solicitation Message Interval

Table 26-2 lists the release history for this feature.

**Table 26-2** Feature History for Neighbor Solicitation Message Interval

| Feature Name                           | Releases | Feature Information                                                                              |
|----------------------------------------|----------|--------------------------------------------------------------------------------------------------|
| Neighbor solicitation message interval | 7.0(1)   | <p>The feature was introduced.</p> <p>The <b>ipv6 nd ns-interval</b> command was introduced.</p> |

## Configuring the Neighbor Reachable Time

This section includes the following topics:

- [Information About Neighbor Reachable Time, page 26-5](#)
- [Licensing Requirements for Neighbor Reachable Time, page 26-5](#)
- [Guidelines and Limitations for Neighbor Reachable Time, page 26-5](#)
- [Default Settings for the Neighbor Reachable Time, page 26-5](#)
- [Configuring Neighbor Reachable Time, page 26-6](#)
- [Feature History for Neighbor Reachable Time, page 26-7](#)

## Information About Neighbor Reachable Time

The neighbor reachable time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly, however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

## Licensing Requirements for Neighbor Reachable Time

The following table shows the licensing requirements for this feature:

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Guidelines and Limitations for Neighbor Reachable Time

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported in routed mode only. Transparent mode is not supported.

### Additional Guidelines and Limitations

- The interval value is included in all IPv6 router advertisements sent out this interface.
- The configured time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly; however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

## Default Settings for the Neighbor Reachable Time

Table 26-3 lists the default settings for neighbor reachable time parameters.

**Table 26-3** Default Neighbor Reachable Time Parameters

| Parameters                            | Default           |
|---------------------------------------|-------------------|
| <i>value</i> (time mode is reachable) | The default is 0. |

## Configuring Neighbor Reachable Time

To configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred, enter the following command:

| Command                                                                              | Purpose                                                                                                                                                                                                                                    |
|--------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ipv6 nd reachable-time value</code>                                            | Sets the amount of time that a remote IPv6 node is reachable.                                                                                                                                                                              |
| <b>Example:</b><br>hostname (config-if)# <code>ipv6 nd reachable-time 1700000</code> | Valid values for the <i>value</i> argument range from 0 to 3600000 milliseconds.<br>When 0 is used for the value, the reachable time is sent as undetermined. It is up to the receiving devices to set and track the reachable time value. |

### Examples

The following example configures an IPv6 reachable time of 1700000 milliseconds for the selected interface, GigabitEthernet 0/0:

```
hostname (config)# interface gigabitethernet 0/0
hostname (config-if)# ipv6 nd reachable-time 1700000
```

## Monitoring Neighbor Reachable Time

To monitor IPv6 neighbor reachable time, enter the following command:

| Command                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <code>show ipv6 interface</code> | Displays the usability status of interfaces configured for IPv6. Including the interface name, such as “outside,” displays the settings for the specified interface. Excluding the name from the command displays the settings for all interfaces that have IPv6 enabled on them. Output for the command shows the following: <ul style="list-style-type: none"> <li>• The name and status of the interface.</li> <li>• The link-local and global unicast addresses.</li> <li>• The multicast groups to which the interface belongs.</li> <li>• ICMP redirect and error message settings.</li> <li>• Neighbor discovery settings.</li> <li>• The actual time when the command is set to 0.</li> <li>• The neighbor discovery reachable time that is being used.</li> </ul> |

## Feature History for Neighbor Reachable Time

Table 26-4 lists the release history for this feature.

**Table 26-4** Feature History for Neighbor Reachable Time

| Feature Name                           | Releases | Feature Information                                                                         |
|----------------------------------------|----------|---------------------------------------------------------------------------------------------|
| Neighbor solicitation message interval | 7.0(1)   | The feature was introduced.<br>The <code>ipv6 nd ns-interval</code> command was introduced. |

## Configuring Router Advertisement Messages

An adaptive security appliance can participate in router advertisements so that neighboring devices can dynamically learn a default router address.

This section includes the following topics:

- [Information About Router Advertisement Messages, page 26-7](#)
- [Configuring the Router Advertisement Transmission Interval, page 26-8](#)
- [Configuring the Router Lifetime Value, page 26-11](#)
- [Configuring the IPv6 Prefix, page 26-13](#)
- [Suppressing Router Advertisement Messages, page 26-18](#)

## Information About Router Advertisement Messages

An adaptive security appliance can participate in router advertisements so that neighboring devices can dynamically learn a default router address. Router advertisement messages (ICMPv6 Type 134) are periodically sent out each IPv6 configured interface of the adaptive security appliance. The router advertisement messages are sent to the all-nodes multicast address.

**Figure 26-2** IPv6 Neighbor Discovery—Router Advertisement Message

Router advertisement packet definitions:

ICMPv6 Type = 134

Src = router link-local address

Dst = all-nodes multicast address

Data = options, prefix, lifetime, autoconfig flag

132917

Router advertisement messages typically include the following information:

- One or more IPv6 prefix that nodes on the local link can use to automatically configure their IPv6 addresses.

- Lifetime information for each prefix included in the advertisement.
- Sets of flags that indicate the type of autoconfiguration (stateless or stateful) that can be completed.
- Default router information (whether the router sending the advertisement should be used as a default router and, if so, the amount of time (in seconds) the router should be used as a default router).
- Additional information for hosts, such as the hop limit and MTU a host should use in packets that it originates.
- The amount of time between neighbor solicitation message retransmissions on a given link.
- The amount of time a node considers a neighbor reachable.

Router advertisements are also sent in response to router solicitation messages (ICMPv6 Type 133). Router solicitation messages are sent by hosts at system startup so that the host can immediately autoconfigure without needing to wait for the next scheduled router advertisement message. Because router solicitation messages are usually sent by hosts at system startup, and the host does not have a configured unicast address, the source address in router solicitation messages is usually the unspecified IPv6 address (0:0:0:0:0:0:0:0). If the host has a configured unicast address, the unicast address of the interface sending the router solicitation message is used as the source address in the message. The destination address in router solicitation messages is the all-routers multicast address with a scope of the link. When a router advertisement is sent in response to a router solicitation, the destination address in the router advertisement message is the unicast address of the source of the router solicitation message.

You can configure the following settings for router advertisement messages:

- The time interval between periodic router advertisement messages.
- The router lifetime value, which indicates the amount of time IPv6 nodes should consider the adaptive security appliance to be the default router.
- The IPv6 network prefixes in use on the link.
- Whether or not an interface transmits router advertisement messages.

Unless otherwise noted, the router advertisement message settings are specific to an interface and are entered in interface configuration mode. See the following topics for information about changing these settings:

- [Configuring the Router Advertisement Transmission Interval, page 26-8](#)
- [Configuring the Router Lifetime Value, page 26-11](#)
- [Configuring the IPv6 Prefix, page 26-13](#)
- [Suppressing Router Advertisement Messages, page 26-17](#)

## Configuring the Router Advertisement Transmission Interval

This section shows how to configure the interval between IPv6 router advertisement transmissions on an interface and includes the following topics:

- [Licensing Requirements for Router Advertisement Transmission Interval, page 26-9](#)
- [Guidelines and Limitations for the Router Advertisement Transmission Interval, page 26-9](#)
- [Default Settings for Router Advertisement Transmission Interval, page 26-9](#)
- [Configuring Router Advertisement Transmission Interval, page 26-9](#)
- [Monitoring the Router Advertisement Transmission Interval, page 26-10](#)
- [Feature History for the Router Advertisement Transmission Interval, page 26-10](#)

## Licensing Requirements for Router Advertisement Transmission Interval

The following table shows the licensing requirements for this feature:

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Guidelines and Limitations for the Router Advertisement Transmission Interval

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported in routed mode only. Transparent mode is not supported.

### Additional Guidelines and Limitations

The interval between transmissions should be less than or equal to the IPv6 router advertisement lifetime if the adaptive security appliance is configured as a default router. by using the **ipv6 nd ra-lifetime** command. To prevent synchronization with other IPv6 nodes, randomly adjust the actual value used to within 20 percent of the specified value.

## Default Settings for Router Advertisement Transmission Interval

Table 26-5 lists the default settings for neighbor reachable time parameters.

**Table 26-5** Default Router Advertisement Transmission Interval Parameters

| Parameters                                    | Default                     |
|-----------------------------------------------|-----------------------------|
| <i>value</i> (interval between transmissions) | The default is 200 seconds. |

## Configuring Router Advertisement Transmission Interval

To configure the interval between IPv6 router advertisement transmissions on an interface, enter the following command:

| Command                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv6 nd ra-interval</b> [ <b>msec</b> ] <i>value</i><br><br><b>Example:</b><br>hostname (config-if)# <b>ipv6 nd ra-interval</b> 201 | Sets the interval between IPv6 router advertisement transmissions.<br><br>The optional <b>msec</b> keyword indicates that the value provided is in milliseconds. If this keyword is not present, the value provided is in seconds.<br><br>Valid values for the <i>value</i> argument range from 3 to 1800 seconds or from 500 to 1800000 milliseconds if the msec keyword is provided. |

### Examples

The following example configures an IPv6 router advertisement interval of 201 seconds for the selected interface, GigabitEthernet 0/0:

```
hostname (config)# interface gigabitethernet 0/0
hostname (config-if)# ipv6 nd ra-interval 201
```

### Monitoring the Router Advertisement Transmission Interval

To monitor IPv6 neighbor reachable time, enter the following command:

| Command                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>show ipv6 interface</code> | <p>Displays the usability status of interfaces configured for IPv6. Including the interface name, such as “outside,” displays the settings for the specified interface. Excluding the name from the command displays the settings for all interfaces that have IPv6 enabled on them. Output for the command shows the following:</p> <ul style="list-style-type: none"> <li>• The name and status of the interface.</li> <li>• The link-local and global unicast addresses.</li> <li>• The multicast groups to which the interface belongs.</li> <li>• ICMP redirect and error message settings.</li> <li>• Neighbor discovery settings.</li> <li>• The actual time when the command is set to 0.</li> <li>• The neighbor discovery reachable time that is being used.</li> </ul> |

### Feature History for the Router Advertisement Transmission Interval

Table 26-6 lists the release history for this feature.

**Table 26-6** Feature History for Router Advertisement Transmission Interval

| Feature Name                               | Releases | Feature Information                                                                              |
|--------------------------------------------|----------|--------------------------------------------------------------------------------------------------|
| Router advertisement transmission interval | 7.0(1)   | <p>The feature was introduced.</p> <p>The <b>ipv6 nd ra-interval</b> command was introduced.</p> |

## Configuring the Router Lifetime Value

This section shows how to configure the interval between IPv6 router advertisement transmissions on an interface and includes the following topics:

- [Licensing Requirements for the Router Lifetime Value, page 26-11](#)
- [Guidelines and Limitations for the Router Lifetime Value, page 26-11](#)
- [Default Settings for the Router Lifetime Value, page 26-11](#)
- [Configuring the Router Lifetime Value, page 26-11](#)
- [Feature History for the Router Lifetime Value, page 26-13](#)

### Licensing Requirements for the Router Lifetime Value

The following table shows the licensing requirements for this feature:

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

### Guidelines and Limitations for the Router Lifetime Value

This section includes the guidelines and limitations for this feature.

#### Context Mode Guidelines

Supported in single and multiple context mode.

#### Firewall Mode Guidelines

Supported in routed mode only. Transparent mode is not supported.

#### Additional Guidelines and Limitations

The interval between transmissions should be less than or equal to the IPv6 router advertisement lifetime if the adaptive security appliance is configured as a default router by using the **ipv6 nd ra-lifetime** command. To prevent synchronization with other IPv6 nodes, randomly adjust the actual value used to within 20 percent of the specified value.

### Default Settings for the Router Lifetime Value

[Table 26-7](#) lists the default settings for neighbor reachable time parameters.

**Table 26-7** Default Router Advertisement Transmission Interval Parameters

| Parameters                                    | Default                     |
|-----------------------------------------------|-----------------------------|
| <i>value</i> (interval between transmissions) | The default is 200 seconds. |

### Configuring the Router Lifetime Value

To configure the interval between IPv6 router advertisement transmissions on an interface, enter the following command:

| Command                                                                           | Purpose                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv6 nd ra-interval</b> [ <i>msec</i> ] <i>value</i>                           | Sets the interval between IPv6 router advertisement transmissions.                                                                                                                                                                                                                                           |
| <b>Example:</b><br>hostname (config-if)# <b>ipv6 nd ra-interval</b><br><b>201</b> | The optional <b>msec</b> keyword indicates that the value provided is in milliseconds. If this keyword is not present, the value provided is in seconds.<br><br>Valid values for the <i>value</i> argument range from 3 to 1800 seconds or from 500 to 1800000 milliseconds if the msec keyword is provided. |

### Examples

The following example configures an IPv6 router advertisement interval of 201 seconds for the selected interface, GigabitEthernet 0/0:

```
hostname (config)# interface gigabitethernet 0/0
hostname (config-if)# ipv6 nd ra-interval 201
```

## Monitoring the Router Lifetime Value

To monitor IPv6 neighbor reachable time, enter the following command:

| Command                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>show ipv6 interface</b> | Displays the usability status of interfaces configured for IPv6. Including the interface name, such as “outside,” displays the settings for the specified interface. Excluding the name from the command displays the settings for all interfaces that have IPv6 enabled on them. Output for the command shows the following: <ul style="list-style-type: none"> <li>• The name and status of the interface.</li> <li>• The link-local and global unicast addresses.</li> <li>• The multicast groups to which the interface belongs.</li> <li>• ICMP redirect and error message settings.</li> <li>• Neighbor discovery settings.</li> <li>• The actual time when the command is set to 0.</li> <li>• The neighbor discovery reachable time that is being used.</li> </ul> |

## Where to Go Next

Configure the router lifetime value in IPv6 router advertisements on an interface with the **ipv6 nd ra-lifetime** command.

## Feature History for the Router Lifetime Value

Table 26-8 lists the release history for this feature.

**Table 26-8** Feature History for Router Advertisement Transmission Interval

| Feature Name                               | Releases | Feature Information                                    |
|--------------------------------------------|----------|--------------------------------------------------------|
| Router advertisement transmission interval | 7.0(1)   | The feature was introduced.                            |
|                                            |          | The <b>ipv6 nd ra-interval</b> command was introduced. |

## Configuring the IPv6 Prefix

Stateless autoconfiguration uses IPv6 prefixes provided in router advertisement messages to create the global unicast address from the link-local address. The prefix advertisement can be used by neighboring devices to autoconfigure their interface addresses. You can configure which IPv6 prefixes are included in IPv6 router advertisements.

This section shows how to configure IPv6 prefixes and includes the following topics:

- [Licensing Requirements for IPv6 Prefixes, page 26-13](#)
- [Guidelines and Limitations for IPv6 Prefixes, page 26-13](#)
- [Default Settings for IPv6 Prefixes, page 26-14](#)
- [Configuring IPv6 Prefixes, page 26-15](#)

## Licensing Requirements for IPv6 Prefixes

The following table shows the licensing requirements for this feature:

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Guidelines and Limitations for IPv6 Prefixes

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported in routed mode only. Transparent mode is not supported.

### Additional Guidelines and Limitations

The **ipv6 nd prefix** command allows control over the individual parameters per prefix, including whether or not the prefix should be advertised.

By default, prefixes configured as addresses on an interface using the **ipv6 address** command are advertised in router advertisements. If you configure prefixes for advertisement using the **ipv6 nd prefix** command, then only these prefixes are advertised.

The **default** keyword can be used to set default parameters for all prefixes.

A date can be set to specify the expiration of a prefix. The valid and preferred lifetimes are counted down in real time. When the expiration date is reached, the prefix will no longer be advertised.

When onlink is on (by default), the specified prefix is assigned to the link. Nodes sending traffic to such addresses that contain the specified prefix consider the destination to be locally reachable on the link.

When autoconfig is on (by default), it indicates to hosts on the local link that the specified prefix can be used for IPv6 autoconfiguration.

For stateless autoconfiguration to work correctly, the advertised prefix length in router advertisement messages must always be 64 bits.

## Default Settings for IPv6 Prefixes

Table 26-9 lists the default settings for neighbor reachable time parameters.

**Table 26-9**      *Default for IPv6 Prefixes Parameters*

| Parameters      | Default                                                                                                |
|-----------------|--------------------------------------------------------------------------------------------------------|
| prefix lifetime | The default lifetime is 2592000 seconds (30 days) and a preferred lifetime is 604800 seconds (7 days). |
| on-link flag    | The flag is on by default, which means that the prefix is used on the advertising interface.           |
| autoconfig flag | The flag is on by default, which means that the prefix is used for autoconfiguration.                  |

## Configuring IPv6 Prefixes

To configure the which IPv6 prefixes are included in IPv6 router advertisements, enter the following command:

| Command                                                                                                                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>ipv6 nd prefix ipv6-prefix/prefix-length   default [[valid-lifetime preferred-lifetime]   [at valid-date preferred-date]   infinite   no-advertise   off-link   no-autoconfig]</pre> <p><b>Example:</b></p> <pre>hostname (config-if)# ipv6 nd prefix 2001:200:200::/35 1000 900</pre> | <p>Configures which IPv6 prefixes are included in IPv6 router advertisements.</p> <p>The <b>at valid-date preferred-date</b> syntax indicates the date and time at which the lifetime and preference expire. The prefix is valid until this specified date and time are reached. Dates are expressed in the form <i>date-valid-expire month-valid-expire hh:mm-valid-expire date-prefer-expire month-prefer-expire hh:mm-prefer-expire</i>.</p> <p>The <b>default</b> keyword indicates that default values are used.</p> <p>The optional <b>infinite</b> keyword specifies that the valid lifetime does not expire.</p> <p>The <i>ipv6-prefix</i> argument specifies the IPv6 network number to include in router advertisements. This argument must be in the form documented in RFC 2373 where the address is specified in hexadecimal using 16-bit values between colons.</p> <p>The optional <b>no-advertise</b> keyword indicates to hosts on the local link that the specified prefix is not to be used for IPv6 autoconfiguration.</p> <p>The optional <b>no-autoconfig</b> keyword indicates to hosts on the local link that the specified prefix cannot be used for IPv6 autoconfiguration.</p> <p>The optional <b>off-link</b> keyword indicates that the specified prefix is not used for on-link determination.</p> <p>The <i>preferred-lifetime</i> argument specifies the amount of time (in seconds) that the specified IPv6 prefix is advertised as being preferred. Valid values range from 0 to 4294967295 seconds. The maximum value represents infinity, which can also be specified with infinite. The default is 604800 (7 days).</p> <p>The <i>prefix-length</i> argument specifies the length of the IPv6 prefix. This value indicates how many of the high-order, contiguous bits of the address comprise the network portion of the prefix. The slash (/) must precede the prefix length.</p> <p>The <i>valid-lifetime</i> argument specifies the amount of time that the specified IPv6 prefix is advertised as being valid. Valid values range from 0 to 4294967295 seconds. The maximum value represents infinity, which can also be specified with infinite. The default is 2592000 (30 days).</p> |

### Examples

The following example includes the IPv6 prefix 2001:200::/35, with a valid lifetime of 1000 seconds and a preferred lifetime of 900 seconds, in router advertisements sent out on the specified interface, which is GigabitEthernet 0/0:

```
hostname (config)# interface gigabitethernet 0/0
hostname (config-if)# ipv6 nd prefix 2001:200:200::/35 1000 900
```

| Command                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>show ipv6 interface</code> | <p>Displays the usability status of interfaces configured for IPv6. Including the interface name, such as “outside,” displays the settings for the specified interface. Excluding the name from the command displays the settings for all interfaces that have IPv6 enabled on them. Output for the command shows the following:</p> <ul style="list-style-type: none"><li>• The name and status of the interface.</li><li>• The link-local and global unicast addresses.</li><li>• The multicast groups to which the interface belongs.</li><li>• ICMP redirect and error message settings.</li><li>• Neighbor discovery settings.</li><li>• The actual time when the command is set to 0.</li><li>• The neighbor discovery reachable time that is being used.</li></ul> |

The command argument <i>ipv6-prefix</i> indicates this network number, where the address must be specified in hexadecimal using 16-bit values between colons. | IP Version 6 Addressing Architecture |

## Feature History for IPv6 Prefixes

Table 26-10 lists the release history for this feature.

**Table 26-10** Feature History for Router Advertisement Transmission Interval

| Feature Name                               | Releases | Feature Information                                                              |
|--------------------------------------------|----------|----------------------------------------------------------------------------------|
| Router advertisement transmission interval | 7.0(1)   | The feature was introduced.<br>The <b>ipv6 nd prefix</b> command was introduced. |

## Suppressing Router Advertisement Messages

By default, router advertisement messages are automatically sent in response to router solicitation messages. You may want to disable these messages on any interface for which you do not want the adaptive security appliance to supply the IPv6 prefix (for example, the outside interface).

This section shows how to suppress IPv6 router advertisement transmissions on an interface and includes the following topics:

- [Licensing Requirements for Suppressing Router Advertisement Messages, page 26-17](#)
- [Guidelines and Limitations for Suppressing Router Advertisement Messages, page 26-18](#)
- [Default Settings for Suppressing Router Advertisement Messages, page 26-18](#)
- [Suppressing Router Advertisement Messages, page 26-18](#)
- [Feature History for Suppressing Router Advertisement Messages, page 26-19](#)

## Licensing Requirements for Suppressing Router Advertisement Messages

The following table shows the licensing requirements for this feature:

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Guidelines and Limitations for Suppressing Router Advertisement Messages

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported in routed mode only. Transparent mode is not supported.

### Additional Guidelines and Limitations

The router lifetime value is included in all IPv6 router advertisements sent out the interface. The value indicates the usefulness of the adaptive security appliance as a default router on this interface.

Setting the value to a non-zero value indicates that the adaptive security appliance should be considered a default router on this interface. The no-zero value for the router lifetime value should not be less than the router advertisement interval.

## Default Settings for Suppressing Router Advertisement Messages

Table 26-11 lists the default settings for neighbor reachable time parameters.

**Table 26-11**      *Default for Suppressing Router Advertisement Parameters*

| Parameters      | Default                                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| router lifetime | The default lifetime is 1800 seconds. Setting the value to 0 indicates that the adaptive security appliance should not be considered a default router on this interface. |

## Suppressing Router Advertisement Messages

To configure the router lifetime value in IPv6 router advertisements on an interface, enter the following command:

| Command                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ipv6 nd ra-lifetime <i>seconds</i></code><br><br><b>Example:</b><br><code>hostname (config-if)# ipv6 nd prefix 2001:200:200::/35 1000 900</code> | <p>Configures the router lifetime value.</p> <p>The <i>seconds</i> argument specifies the validity of the adaptive security appliance as a default router on this interface. Valid values range from 0 to 9000 seconds. The default is 1800 seconds. 0 indicates that the adaptive security appliance should not be considered a default router on the specified interface.</p> <p>Entering this command causes the adaptive security appliance to appear as a regular IPv6 neighbor on the link and not as an IPv6 router.</p> |

## Examples

The following example configures an IPv6 router advertisement lifetime of 1801 seconds for the specified interface, which is GigabitEthernet 0/0:

```
hostname (config)# interface gigabitethernet 0/0
hostname (config-if)# ipv6 nd ra-lifetime 1801
```

| Command                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>show ipv6 interface</code> | <p>Displays the usability status of interfaces configured for IPv6. Including the interface name, such as outside, displays the settings for the specified interface. Excluding the name from the command displays the settings for all interfaces that have IPv6 enabled on them. Output for the command shows the following:</p> <ul style="list-style-type: none"> <li>• The name and status of the interface.</li> <li>• The link-local and global unicast addresses.</li> <li>• The multicast groups to which the interface belongs.</li> <li>• ICMP redirect and error message settings.</li> <li>• Neighbor discovery settings.</li> <li>• The actual time when the command is set to 0.</li> <li>• The neighbor discovery reachable time that is being used.</li> </ul> |

## Feature History for Suppressing Router Advertisement Messages

## Information About a Static IPv6 Neighbor

You can manually define a neighbor in the IPv6 neighbor cache. If an entry for the specified IPv6 address already exists in the neighbor discovery cache—learned through the IPv6 neighbor discovery process—the entry is automatically converted to a static entry. Static entries in the IPv6 neighbor discovery cache are not modified by the neighbor discovery process.

## Licensing Requirements for Static IPv6 Neighbor

The following table shows the licensing requirements for this feature:

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported in routed mode only. Transparent mode is not supported.

### Additional Guidelines and Limitations

The following guidelines and limitations apply for configuring a static IPv6 neighbor:

- The **ipv6 neighbor** command is similar to the **arp** command. If an entry for the specified IPv6 address already exists in the neighbor discovery cache—learned through the IPv6 neighbor discovery process—the entry is automatically converted to a static entry. These entries are stored in the configuration when the copy command is used to store the configuration.
- Use the **show ipv6 neighbor** command to view static entries in the IPv6 neighbor discovery cache.
- The **clear ipv6 neighbor** command deletes all entries in the IPv6 neighbor discovery cache except static entries. The **no ipv6 neighbor** command deletes a specified static entry from the neighbor discovery cache; the command does not remove dynamic entries—entries learned from the IPv6 neighbor discovery process—from the cache. Disabling IPv6 on an interface by using the **no ipv6 enable** command deletes all IPv6 neighbor discovery cache entries configured for that interface except static entries (the state of the entry changes to INCOMPLETE).
- Static entries in the IPv6 neighbor discovery cache are not modified by the neighbor discovery process.
- The **clear ipv6 neighbor** command does not remove static entries from the IPv6 neighbor discovery cache; it only clears the dynamic entries.

## Default Settings

Table 26-13 lists the default settings for static IPv6 neighbor parameters.

**Table 26-13**     *Default Static IPv6 Neighbor Parameters*

| Parameters           | Default                                                                 |
|----------------------|-------------------------------------------------------------------------|
| Static IPv6 neighbor | Static entries are not configured in the IPv6 neighbor discovery cache. |

## Configuring a Static IPv6 Neighbor

To configure a static entry in the IPv6 neighbor discovery cache, enter the following command:

| Command                                                                                       | Purpose                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv6 neighbor</b> <i>ipv6_address if_name mac_address</i>                                  | Configures a static entry in the IPv6 neighbor discovery cache.                                                                                                                                                                                          |
| <b>Example:</b><br>hostname)config-if)# <b>ipv6 neighbor 3001:1::45A inside 002.7D1A.9472</b> | The <i>ipv6_address</i> argument is the link-local IPv6 address of the neighbor, the <i>if_name</i> argument is the interface through which the neighbor is available, and the <i>mac_address</i> argument is the MAC address of the neighbor interface. |

### Examples

The following example adds a static entry for an inside host with an IPv6 address of 3001:1::45A and a MAC address of 002.7D1a.9472 to the neighbor discovery cache:

```
hostname)config-if)# ipv6 neighbor 3001:1::45A inside 002.7D1A.9472
```

## Monitoring Neighbor Solicitation Messages

To monitor IPv6 neighbor discovery, enter the following command:

| Command                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>show ipv6 interface</code> | <p>Displays the usability status of interfaces configured for IPv6. Including the interface name, such as outside, displays the settings for the specified interface. Excluding the name from the command displays the settings for all interfaces that have IPv6 enabled on them. Output for the command shows the following:</p> <ul style="list-style-type: none"> <li>• The name and status of the interface.</li> <li>• The link-local and global unicast addresses.</li> <li>• The multicast groups to which the interface belongs.</li> <li>• ICMP redirect and error message settings.</li> <li>• Neighbor discovery settings.</li> </ul> |

## Feature History for Configuring a Static IPv6 Neighbor

Table 26-14 lists the release history for this feature.

**Table 26-14**      *Feature History for Configuring a Static IPv6 Neighbor*

| Feature Name         | Releases | Feature Information                                                                        |
|----------------------|----------|--------------------------------------------------------------------------------------------|
| Static IPv6 Neighbor | 7.0(1)   | <p>The feature was introduced.</p> <p>The <b>ipv6 neighbor</b> command was introduced.</p> |

## **PART 5**

### **Configuring Network Address Translation**

# CHAPTER 27

## Information About NAT

This chapter provides an overview of how Network Address Translation (NAT) works on the adaptive security appliance. This chapter includes the following sections:

- [Why Use NAT?, page 27-1](#)
- [NAT Terminology, page 27-2](#)
- [NAT Types, page 27-2](#)
- [NAT in Routed and Transparent Mode, page 27-12](#)
- [How NAT is Implemented, page 27-15](#)
- [NAT Rule Order, page 27-19](#)
- [Mapped Address Guidelines, page 27-20](#)
- [DNS and NAT, page 27-21](#)
- [Where to Go Next, page 27-23](#)

### Note

To start configuring NAT, see [Chapter 28, “Configuring Network Object NAT,”](#) or [Chapter 29, “Configuring Twice NAT.”](#)

## Why Use NAT?

Each computer and device within an IP network is assigned a unique IP address that identifies the host. Because of a shortage of public IPv4 addresses, most of these IP addresses are private, not routable anywhere outside of the private company network. RFC 1918 defines the private IP addresses you can use internally ([Table 27-1](#)):

**Table 27-1**      **Private IP Addresses**

| Network Class     | Address Block  | Starting Address | Ending Address  | Approximate Hosts |
|-------------------|----------------|------------------|-----------------|-------------------|
| Class A addresses | 10.0.0.0/8     | 10.0.0.0         | 10.255.255.255  | 16,000,000        |
| Class B addresses | 172.16.0.0/12  | 172.16.0.0       | 172.31.255.255  | 1,000,000         |
| Class C addresses | 192.168.0.0/16 | 192.168.0.0      | 192.168.255.255 | 65,000            |

One of the main functions of NAT is to enable private IP networks to connect to the Internet. NAT replaces a private IP address with a public IP address, translating the private addresses in the internal private network into legal, routable addresses that can be used on the public Internet. In this way, NAT conserves public addresses because it can be configured to advertise only one public address for the entire network to the outside world.

Other functions of NAT include:

- Security—Keeping internal IP addresses hidden discourages direct attacks.
- IP routing solutions—Overlapping IP addresses are not a problem when you use NAT.
- Flexibility—You can change internal IP addressing schemes without affecting the public addresses available externally; for example, for a server accessible to the Internet, you can maintain a fixed IP address for Internet use, but internally, you can change the server address.

## NAT Terminology

This document uses the following terminology:

- Real address/host/network/interface—The real address is the address that is defined on the host, before it is translated. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, then the inside network would be the “real” network. Note that you can translate any network connected to the adaptive security appliance, not just an inside network. Therefore if you configure NAT to translate outside addresses, “real” can refer to the outside network when it accesses the inside network.
- Mapped address/host/network/interface—The mapped address is the address that the real address is translated to. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, then the outside network would be the “mapped” network.
- Bidirectional initiation—Static NAT allows connections to be initiated *bidirectionally*, meaning both to the host and from the host.
- Source and destination NAT—For any given packet, both the source and destination IP addresses are compared to the NAT rules, and one or both can be translated/untranslated.

## NAT Types

You can implement NAT using the following methods:

- Static NAT—A consistent mapping between a real and mapped IP address. Allows bidirectional traffic initiation.
- Dynamic NAT—A group of real IP addresses are mapped to a (usually smaller) group of mapped IP addresses, on a first come, first served basis. Only the real host can initiate traffic.
- Dynamic Port Address Translation (PAT)—A group of real IP addresses are mapped to a single IP address using a unique source port of that IP address.
- Identity NAT—Static NAT lets you translate a real address to itself, essentially bypassing NAT. You might want to configure NAT this way when you want to translate a large group of addresses, but then want to exempt a smaller subset of addresses.

This section includes the following topics:

- [Static NAT, page 27-3](#)
- [Dynamic NAT, page 27-8](#)
- [Dynamic PAT, page 27-10](#)
- [Identity NAT, page 27-11](#)

## Static NAT

This section describes static NAT and includes the following topics:

- [Information About Static NAT, page 27-3](#)
- [Information About Static NAT with Port Translation, page 27-3](#)
- [Information About One-to-Many Static NAT, page 27-6](#)
- [Information About Other Mapping Scenarios \(Not Recommended\), page 27-7](#)

### Information About Static NAT

Static NAT creates a fixed translation of a real address to a mapped address. Because the mapped address is the same for each consecutive connection, static NAT allows bidirectional connection initiation, both to and from the host (if an access rule exists that allows it). With dynamic NAT and PAT, on the other hand, each host uses a different address or port for each subsequent translation, so bidirectional initiation is not supported.

[Figure 27-1](#) shows a typical static NAT scenario. The translation is always active so both real and remote hosts can initiate connections.

**Figure 27-1**      **Static NAT**

### Information About Static NAT with Port Translation

Static NAT with port translation lets you specify a real and mapped protocol (TCP or UDP) and port.

This section includes the following topics:

- [Information About Static NAT with Port Address Translation, page 27-4](#)
- [Static NAT with Identity Port Translation, page 27-5](#)
- [Static NAT with Port Translation for Non-Standard Ports, page 27-5](#)
- [Static Interface NAT with Port Translation, page 27-5](#)

## Information About Static NAT with Port Address Translation

When you specify the port with static NAT, you can choose to map the port to the same value or to a different value. Using the same value lets you translate ipA/port1 to ipX/port1 while translating ipA/port2 to ipY/port2.

Figure 27-2 shows a typical static NAT with port translation scenario showing both a port that is mapped to itself and a port that is mapped to a different value. The translation is always active so both translated and remote hosts can initiate connections.

**Figure 27-2** Typical Static NAT with Port Translation Scenario

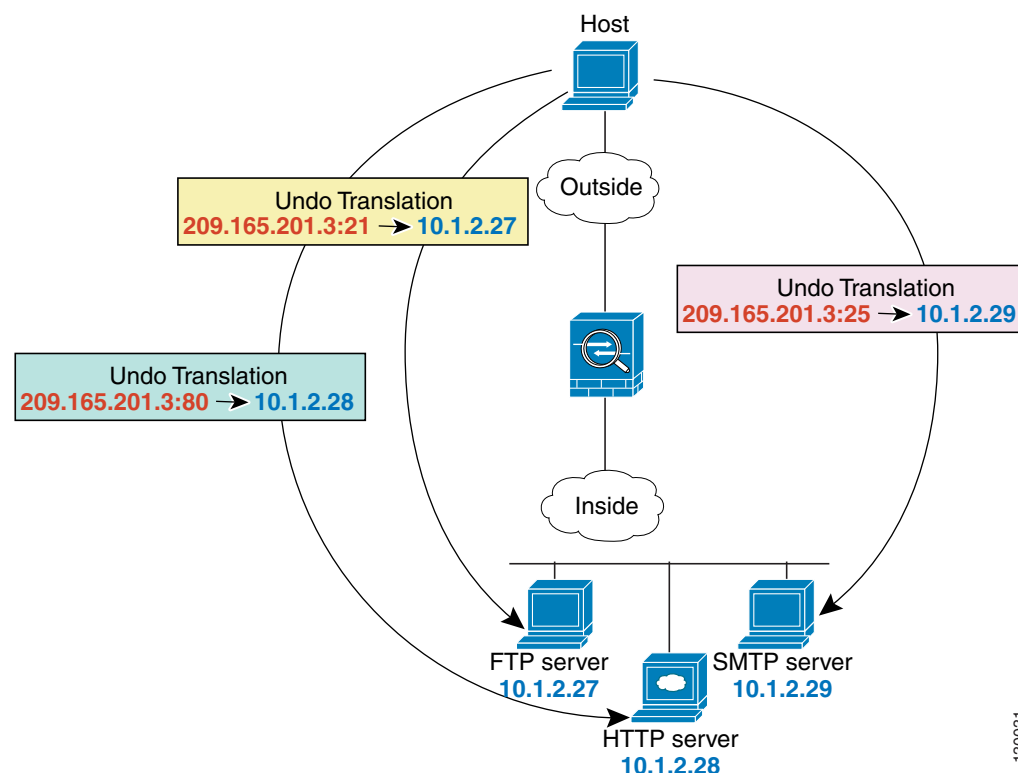

**Note**

For applications that require application inspection for secondary channels (for example, FTP and VoIP), the adaptive security appliance automatically translates the secondary ports.

## Static NAT with Identity Port Translation

The following static NAT with port translation example provides a single address for remote users to access FTP, HTTP, and SMTP. These servers are actually different devices on the real network, but for each server, you can specify static NAT with port translation rules that use the same mapped IP address, but different ports. (See [Figure 27-3](#). See the “[Single Address for FTP, HTTP, and SMTP \(Static NAT with Port Translation\)](#)” section on page 28-16 for details on how to configure this example.)

**Figure 27-3** Static NAT with Port Translation

## Static NAT with Port Translation for Non-Standard Ports

You can also use static NAT with port translation to translate a well-known port to a non-standard port or vice versa. For example, if inside web servers use port 8080, you can allow outside users to connect to port 80, and then undo translation to the original port 8080. Similarly, to provide extra security, you can tell web users to connect to non-standard port 6785, and then undo translation to port 80.

## Static Interface NAT with Port Translation

You can configure static NAT to map a real address to an interface address/port combination. For example, if you want to redirect Telnet access to the adaptive security appliance outside port to an inside IP address (for example, a router interface), then you can map the inside IP address on port 23 to the interface address on port 23. (Note that Telnet is not allowed to the lowest security interface normally; static NAT with interface port translation redirects the disallowed Telnet session instead of denying it).

## Information About One-to-Many Static NAT

Typically, you configure static NAT with a one-to-one mapping. However, in some cases, you might want to configure a single real address to several mapped addresses (one-to-many). When you configure one-to-many static NAT, when the real host initiates traffic, it always uses the first mapped address. However, for traffic initiated to the host, you can initiate traffic to any of the mapped addresses, and they will be untranslated to the single real address.

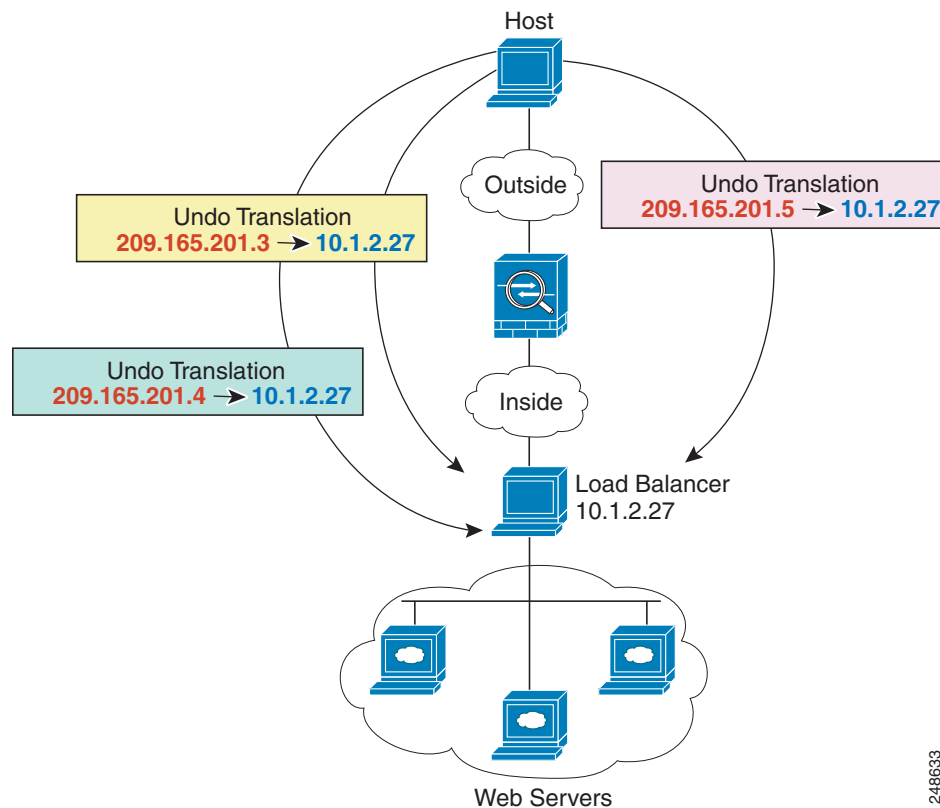

Figure 27-4 shows a typical one-to-many static NAT scenario. The first translation is always active so both translated and remote hosts can initiate connections, but the subsequent mappings are unidirectional to the real host.

**Figure 27-4** One-to-Many Static NAT

For example, you have a load balancer at 10.1.2.27; depending on the URL requested, it redirects traffic to the correct web server. (See [Figure 27-5](#). See the “[Inside Load Balancer with Multiple Mapped Addresses \(Static NAT, One-to-Many\)](#)” section on page 28-15 for details on how to configure this example.)

**Figure 27-5** *One-to-Many Static NAT*

248633

## Information About Other Mapping Scenarios (Not Recommended)

The adaptive security appliance has the flexibility to allow any kind of static mapping scenario: one-to-one, one-to-many, but also few-to-many, many-to-few, and many-to-one mappings. These other mapping options, however, might result in unintended consequences. We recommend using only one-to-one or one-to-many mappings.

Functionally, few-to-many is the same as one-to-many; but because the configuration is more complicated, we recommend creating a one-to-many configuration for each real address that requires it. For example, for a few-to-many scenario, the few real addresses are mapped to the many mapped addresses in order (A to 1, B to 2, C to 3). When all real addresses are mapped, the next mapped address is mapped to the first real address, and so on until all mapped addresses are mapped (A to 4, B to 5, C to 6). This results in multiple mapped addresses for each real address. Just like a one-to-many configuration, only the first mappings are bidirectional; subsequent mappings allow traffic to be initiated to the real host, but all traffic from the real host uses only the first mapped address for the source.

Figure 27-6 shows a typical few-to-many static NAT scenario. The first translation for each real address is always active so both translated and remote hosts can initiate connections, but the subsequent mappings are unidirectional to the real hosts.

**Figure 27-6 Few-to-Many Static NAT**

For a many-to-few or many-to-one configuration, where you have more real addresses than mapped addresses, you run out of mapped addresses before you run out of real addresses. Only the mappings between the lowest real IP addresses and the mapped pool result in bidirectional initiation. The remaining higher real addresses can initiate traffic, but traffic cannot be initiated to them (returning traffic for a connection is directed to the correct real address because of the unique 5-tuple (source IP, destination IP, source port, destination port, protocol) for the connection).

**Note**

Many-to-few or many-to-one NAT is not PAT. If two real hosts use the same source port number and go to the same outside server and the same TCP destination port, and both hosts are translated to the same IP address, then both connections will be reset because of an address conflict (the 5-tuple is not unique).

Figure 27-7 shows a typical many-to-few static NAT scenario. The translations between the lowest real addresses and the mapped addresses are always active so both translated and remote hosts can initiate connections, but the mappings for higher IP addresses are unidirectional from the real hosts.

**Figure 27-7 Many-to-Few Static NAT**

Instead of using a static rule this way, we suggest that you create a one-to-one rule for the traffic that needs bidirectional initiation, and then create a dynamic rule for the rest of your addresses.

## Dynamic NAT

This section describes dynamic NAT and includes the following topics:

- [Information About Dynamic NAT, page 27-9](#)

- [Dynamic NAT Disadvantages and Advantages, page 27-10](#)

## Information About Dynamic NAT

Dynamic NAT translates a group of real addresses to a pool of mapped addresses that are routable on the destination network. The mapped pool typically includes fewer addresses than the real group. When a host you want to translate accesses the destination network, the adaptive security appliance assigns the host an IP address from the mapped pool. The translation is created only when the real host initiates the connection. The translation is in place only for the duration of the connection, and a given user does not keep the same IP address after the translation times out. Users on the destination network, therefore, cannot initiate a reliable connection to a host that uses dynamic NAT, even if the connection is allowed by an access rule.

Figure 27-8 shows a typical dynamic NAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back.

**Figure 27-8** *Dynamic NAT*

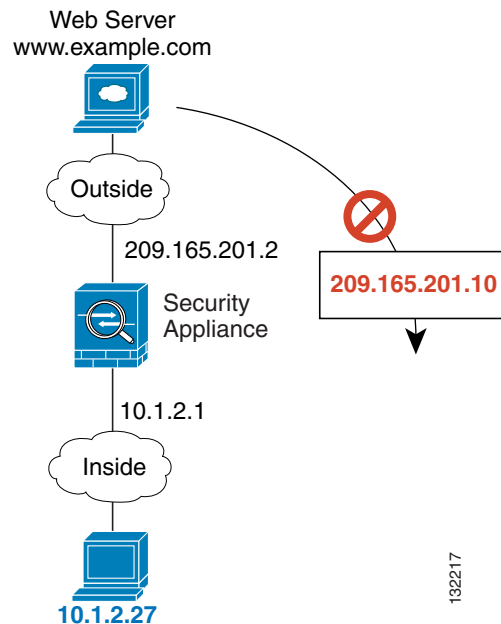

Figure 27-9 shows a remote host attempting to initiate a connection to a mapped address. This address is not currently in the translation table; therefore, the adaptive security appliance drops the packet.

**Figure 27-9** *Remote Host Attempts to Initiate a Connection to a Mapped Address*

**Note**

For the duration of the translation, a remote host can initiate a connection to the translated host if an access rule allows it. Because the address is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule.

## Dynamic NAT Disadvantages and Advantages

Dynamic NAT has these disadvantages:

- If the mapped pool has fewer addresses than the real group, you could run out of addresses if the amount of traffic is more than expected.  
Use PAT if this event occurs often because PAT provides over 64,000 translations using ports of a single address.
- You have to use a large number of routable addresses in the mapped pool; if the destination network requires registered addresses, such as the Internet, you might encounter a shortage of usable addresses.

The advantage of dynamic NAT is that some protocols cannot use PAT. PAT does not work with the following:

- IP protocols that do not have a port to overload, such as GRE version 0.
- Some multimedia applications that have a data stream on one port, the control path on another port, and are not open standard.

See the [“When to Use Application Protocol Inspection” section on page 38-2](#) for more information about NAT and PAT support.

## Dynamic PAT

This section describes dynamic PAT and includes the following topics:

- [Information About Dynamic PAT, page 27-10](#)
- [Dynamic PAT Disadvantages and Advantages, page 27-11](#)

## Information About Dynamic PAT

Dynamic PAT translates multiple real addresses to a single mapped IP address by translating the real address and source port to the mapped address and a unique port above 1024. Each connection requires a separate translation session because the source port differs for each connection. For example, 10.1.1.1:1025 requires a separate translation from 10.1.1.1:1026.

Figure 27-10 shows a typical dynamic PAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back. The mapped address is the same for each translation, but the port is dynamically assigned.

**Figure 27-10**     *Dynamic PAT*

After the connection expires, the port translation also expires after 30 seconds of inactivity. The timeout is not configurable. Users on the destination network cannot reliably initiate a connection to a host that uses PAT (even if the connection is allowed by an access rule).

**Note**

For the duration of the translation, a remote host can initiate a connection to the translated host if an access rule allows it. Because the port address (both real and mapped) is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule.

## Dynamic PAT Disadvantages and Advantages

Dynamic PAT lets you use a single mapped address, thus conserving routable addresses. You can even use the adaptive security appliance interface IP address as the PAT address.

Dynamic PAT does not work with some multimedia applications that have a data stream that is different from the control path. See the [“When to Use Application Protocol Inspection”](#) section on page 38-2 for more information about NAT and PAT support.

## Identity NAT

You might have a NAT configuration in which you need to translate an IP address to itself. For example, if you create a broad rule that applies NAT to every network, but want to exclude one network from NAT, you can create a static NAT rule to translate an address to itself. Identity NAT is necessary for remote access VPN, where you need to exempt the client traffic from NAT.

**Note**

Identity NAT does not perform proxy ARP nor does it allow the specified interface to override the route lookup for a packet.

Figure 27-11 shows a typical identity NAT scenario.

**Figure 27-11 Identity NAT**

## NAT in Routed and Transparent Mode

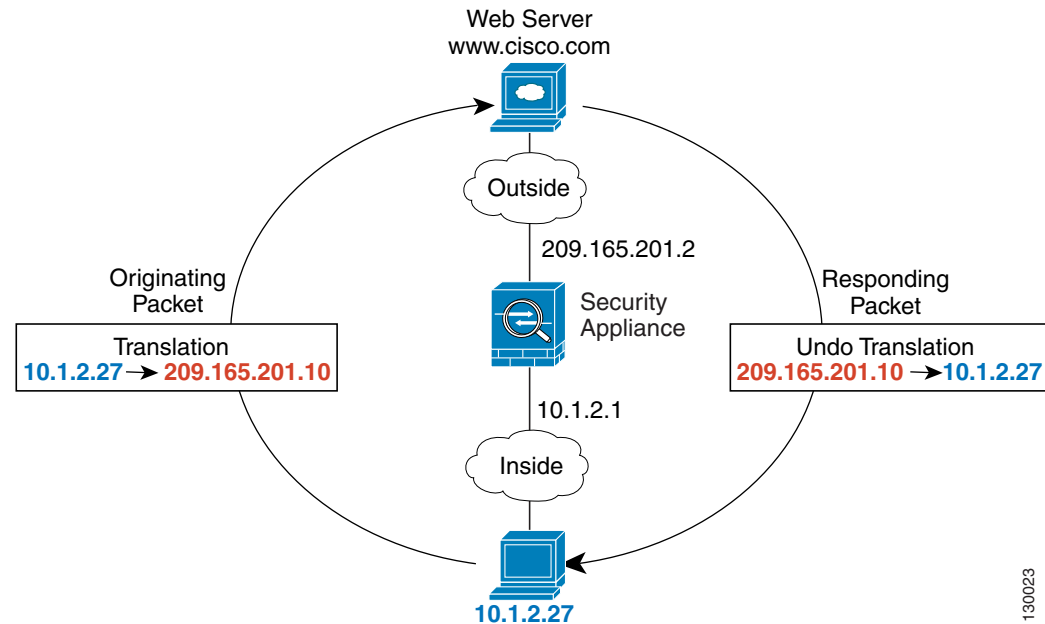

You can configure NAT in both routed and transparent firewall mode. This section describes typical usage for each firewall mode and includes the following topics:

- [NAT in Routed Mode, page 27-13](#)
- [NAT in Transparent Mode, page 27-13](#)

## NAT in Routed Mode

Figure 27-12 shows a typical NAT example in routed mode, with a private network on the inside.

**Figure 27-12 NAT Example: Routed Mode**

1. When the inside host at 10.1.2.27 sends a packet to a web server, the real source address of the packet, 10.1.2.27, is changed to a mapped address, 209.165.201.10.
2. When the server responds, it sends the response to the mapped address, 209.165.201.10, and the adaptive security appliance receives the packet.
3. The adaptive security appliance then changes the translation of the mapped address, 209.165.201.10, back to the real address, 10.1.2.27, before sending it to the host.

## NAT in Transparent Mode

Using NAT in transparent mode eliminates the need for the upstream or downstream routers to perform NAT for their networks.

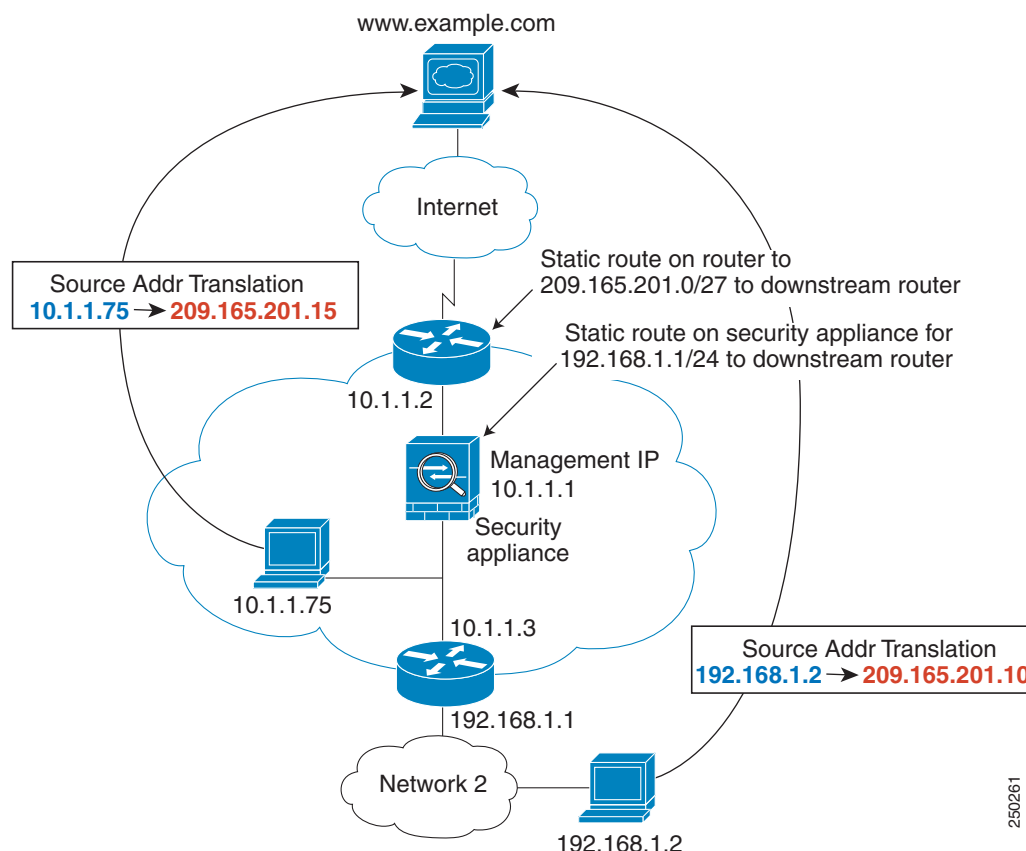

NAT in transparent mode has the following requirements and limitations:

- When the mapped addresses are not on the same network as the transparent firewall, then on the upstream router you need to add a static route for the mapped addresses that points to the downstream router (through the adaptive security appliance).
- When you have VoIP or DNS traffic with NAT and inspection enabled, to successfully translate the IP address inside VoIP and DNS packets, the adaptive security appliance needs to perform a route lookup. Unless the host is on a directly-connected network, then you need to add a static route on the adaptive security appliance for the real host address that is embedded in the packet.
- Because the transparent firewall does not have any interface IP addresses, you cannot use interface PAT.

- ARP inspection is not supported. Moreover, if for some reason a host on one side of the adaptive security appliance sends an ARP request to a host on the other side of the adaptive security appliance, and the initiating host real address is mapped to a different address on the same subnet, then the real address remains visible in the ARP request.

Figure 27-13 shows a typical NAT scenario in transparent mode, with the same network on the inside and outside interfaces. The transparent firewall in this scenario is performing the NAT service so that the upstream router does not have to perform NAT.

**Figure 27-13 NAT Example: Transparent Mode**

1. When the inside host at 10.1.1.75 sends a packet to a web server, the real source address of the packet, 10.1.1.75, is changed to a mapped address, 209.165.201.15.
2. When the server responds, it sends the response to the mapped address, 209.165.201.15, and the adaptive security appliance receives the packet because the upstream router includes this mapped network in a static route directed through the adaptive security appliance.
3. The adaptive security appliance then undoes the translation of the mapped address, 209.165.201.15, back to the real address, 10.1.1.1.75. Because the real address is directly-connected, the adaptive security appliance sends it directly to the host.
4. For host 192.168.1.2, the same process occurs, except that the adaptive security appliance looks up the route in its route table and sends the packet to the downstream router at 10.1.1.3 based on the static route.

# How NAT is Implemented

The adaptive security appliance can implement address translation in two ways: *network object NAT* and *twice NAT*. This section includes the following topics:

- [Main Differences Between Network Object NAT and Twice NAT, page 27-15](#)
- [Information About Network Object NAT, page 27-16](#)
- [Information About Twice NAT, page 27-16](#)

## Main Differences Between Network Object NAT and Twice NAT

The main differences between these two NAT types are:

- How you define the real address.
  - Network object NAT—You define NAT as a parameter for a network object; the network object definition itself provides the real address. This method lets you easily add NAT to network objects. The objects can also be used in other parts of your configuration, for example, for access rules or even in twice NAT rules.
  - Twice NAT—You identify a network object or network object group for both the real and mapped addresses. In this case, NAT is not a parameter of the network object; the network object or group is a parameter of the NAT configuration. The ability to use a network object *group* for the real address means that twice NAT is more scalable.
- How source and destination NAT is implemented.
  - Network object NAT— Each rule can apply to either the source or destination of a packet. So two rules might be used, one for the source IP address, and one for the destination IP address. These two rules cannot be tied together to enforce a specific translation for a source/destination combination.
  - Twice NAT—A single rule translates both the source and destination. A matching packet only matches the one rule, and further rules are not checked. Even if you do not configure the optional destination address for twice NAT, a matching packet still only matches one twice NAT rule. The source and destination are tied together, so you can enforce different translations depending on the source/destination combination. For example, sourceA/destinationA can have a different translation than sourceA/destinationB.
- Order of NAT Rules.
  - Network object NAT—Automatically ordered in the NAT table.
  - Twice NAT—Manually ordered in the NAT table (before or after network object NAT rules).

See the [“NAT Rule Order” section on page 27-19](#) for more information.

We recommend using network object NAT unless you need the extra features that twice NAT provides. Network object NAT is easier to configure, and might be more reliable for applications such as Voice over IP (VoIP). (For VoIP, because twice NAT is applicable only between two objects, you might see a failure in the translation of indirect addresses that do not belong to either of the objects.)

## Information About Network Object NAT

All NAT rules that are configured as a parameter of a network object are considered to be network object NAT rules. Network object NAT is a quick and easy way to configure NAT for a network object, which can be a single IP address, a range of addresses, or a subnet.

After you configure the network object, you can then identify the mapped address for that object, either as an inline address or as another network object or network object group.

When a packet enters the adaptive security appliance, both the source and destination IP addresses are checked against the network object NAT rules. The source and destination address in the packet can be translated by separate rules if separate matches are made. These rules are not tied to each other; different combinations of rules can be used depending on the traffic.

Because the rules are never paired, you cannot specify that sourceA/destinationA should have a different translation than sourceA/destinationB. Use twice NAT for that kind of functionality (twice NAT lets you identify the source and destination address in a single rule).

To start configuring network object NAT, see [Chapter 28, “Configuring Network Object NAT.”](#)

## Information About Twice NAT

Twice NAT lets you identify both the source and destination address in a single rule. Specifying both the source and destination addresses lets you specify that sourceA/destinationA can have a different translation than sourceA/destinationB.

The destination address is optional. If you specify the destination address, you can either map it to itself (identity NAT), or you can map it to a different address. The destination mapping is always a static mapping.

Twice NAT also lets you use service objects for static NAT with port translation; network object NAT only accepts inline definition.

To start configuring twice NAT, see [Chapter 29, “Configuring Twice NAT.”](#)

[Figure 27-14](#) shows a host on the 10.1.2.0/24 network accessing two different servers. When the host accesses the server at 209.165.201.11, the real address is translated to 209.165.202.129. When the host accesses the server at 209.165.200.225, the real address is translated to 209.165.202.130. (See the [“Single Address for FTP, HTTP, and SMTP \(Static NAT with Port Translation\)”](#) section on page 28-16 for details on how to configure this example.)

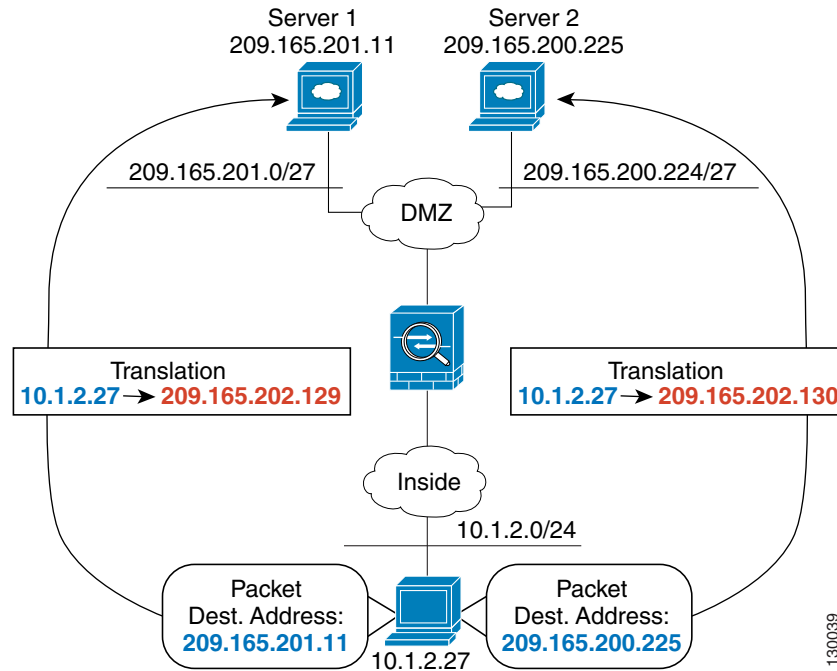

**Figure 27-14** *Twice NAT with Different Destination Addresses*

Figure 27-15 shows the use of source and destination ports. The host on the 10.1.2.0/24 network accesses a single host for both web services and Telnet services. When the host accesses the server for web services, the real address is translated to 209.165.202.129. When the host accesses the same server for Telnet services, the real address is translated to 209.165.202.130.

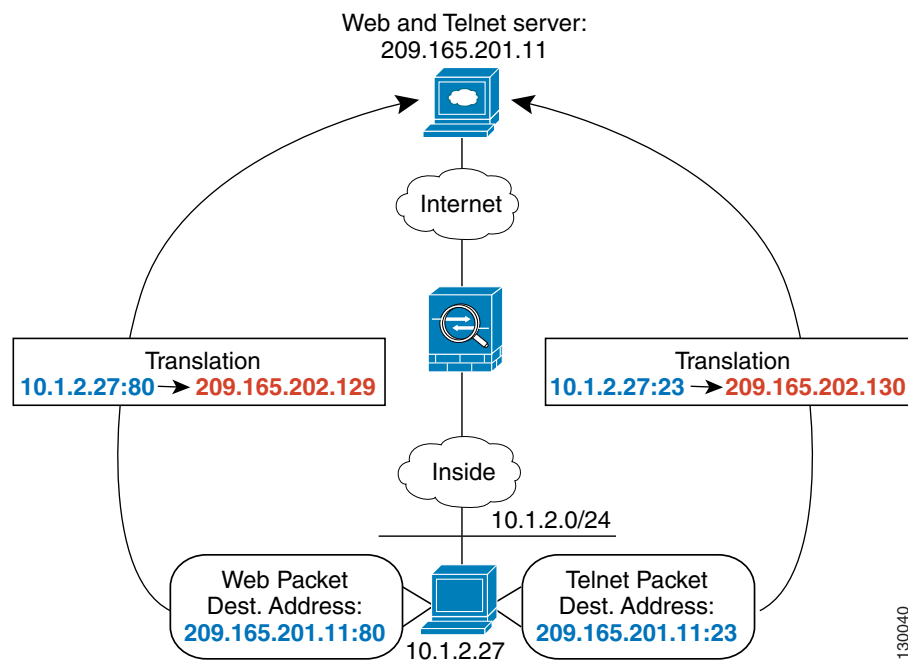

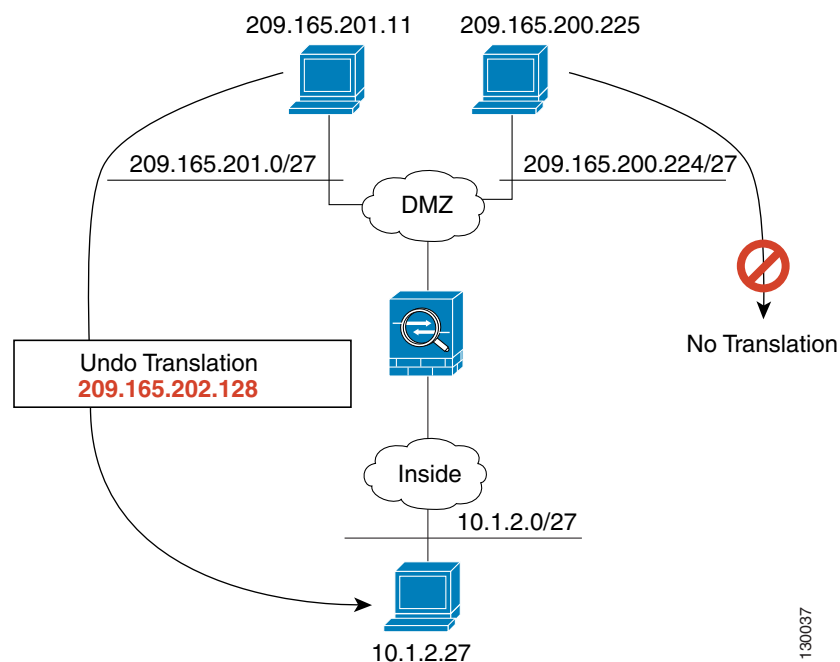

**Figure 27-15** *Twice NAT with Different Destination Ports*

Figure 27-16 shows a remote host connecting to a translated host. The translated host has a twice static NAT translation that translates the real address only for traffic to and from the 209.165.201.0/27 network. A translation does not exist for the 209.165.200.224/27 network, so the translated host cannot connect to that network, nor can a host on that network connect to the translated host.

**Figure 27-16** Twice Static NAT with Destination Address Translation

# NAT Rule Order

Network object NAT rules and twice NAT rules are stored in a single table that is divided into three sections. Section 1 rules are applied first, then section 2, and finally section 3. [Table 27-2](#) shows the order of rules within each section.

**Table 27-2 NAT Rule Table**

| Table Section | Rule Type          | Order of Rules within the Section                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Section 1     | Twice NAT          | <p>Applied on a first match basis, in the order they appear in the configuration. By default, twice NAT rules are added to section 1.</p> <p><b>Note</b> If you configure VPN, the client dynamically adds invisible NAT rules to the end of this section. Be sure that you do not configure a twice NAT rule in this section that might match your VPN traffic, instead of matching the invisible rule. If VPN does not work due to NAT failure, consider adding twice NAT rules to section 3 instead.</p>                                                                                                                                                                                                                                                                                                                                     |
| Section 2     | Network object NAT | <p>Section 2 rules are applied in the following order, as automatically determined by the adaptive security appliance:</p> <ol style="list-style-type: none"> <li>1. Static rules.</li> <li>2. Dynamic rules.</li> </ol> <p>Within each rule type, the following ordering guidelines are used:</p> <ol style="list-style-type: none"> <li>a. Quantity of real IP addresses—From smallest to largest. For example, an object with one address will be assessed before an object with 10 addresses.</li> <li>b. For quantities that are the same, then the IP address number is used, from lowest to highest. For example, 10.1.1.0 is assessed before 11.1.1.0.</li> <li>c. If the same IP address is used, then the name of the network object is used, in alphabetical order. For example, abracadabra is assessed before catwoman.</li> </ol> |
| Section 3     | Twice NAT          | <p>Section 3 rules are applied on a first match basis, in the order they appear in the configuration. You can specify whether to add a twice NAT rule to section 3 when you add the rule.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

For section 2 rules for example, you have the following IP addresses defined within network objects:

```

192.168.1.0/24 (static)
192.168.1.0/24 (dynamic)
10.1.1.0/24 (static)
192.168.1.1/32 (static)
172.16.1.0/24 (dynamic) (object def)
172.16.1.0/24 (dynamic) (object abc)

```

The resultant ordering would be:

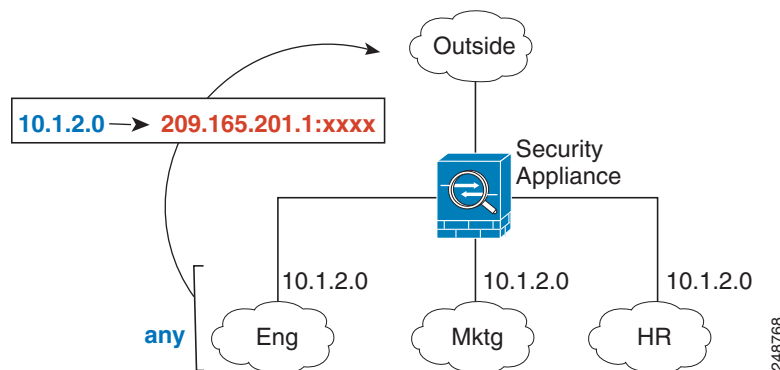

```
192.168.1.1/32 (static)
10.1.1.0/24 (static)
192.168.1.0/24 (static)
172.16.1.0/24 (dynamic) (object abc)
172.16.1.0/24 (dynamic) (object def)
192.168.1.0/24 (dynamic)
```

## NAT Interfaces

You can configure a NAT rule to apply to any interface, or you can identify specific real and mapped interfaces. You can also specify any interface for the real address, and a specific interface for the mapped address, or vice versa.

For example, you might want to specify any interface for the real address and specify the outside interface for the mapped address if you use the same private addresses on multiple interfaces, and you want to translate them all to the same global pool when accessing the outside (Figure 27-17).

**Figure 27-17** Specifying Any Interface

## Mapped Address Guidelines

When you translate the real address to a mapped address, you can use the following mapped addresses:

- Addresses on the same network as the mapped interface.

If you use addresses on the same network as the mapped interface (through which traffic exits the adaptive security appliance), the adaptive security appliance uses proxy ARP to answer any requests for mapped addresses, and thus it intercepts traffic destined for a real address. This solution simplifies routing because the adaptive security appliance does not have to be the gateway for any additional networks. However, this approach does put a limit on the number of available addresses used for translations.

For PAT, you can even use the IP address of the mapped interface.

**Note**

If you configure the mapped interface to be any interface, but you specify a mapped address on the same network as one of the interfaces, then if an ARP request for that mapped address comes in on a *different* interface, then you need to manually configure an ARP entry for that network on the other interface where you specify the interface MAC address (see the **arp** command). Typically, if you specify any interface for the mapped interface, then you use a unique network for the mapped addresses.

- Addresses on a unique network.

If you need more addresses than are available on the mapped interface network, you can identify addresses on a different subnet. The adaptive security appliance uses proxy ARP to answer any requests for mapped addresses, and thus it intercepts traffic destined for a real address.

**Note**

Identity NAT does not perform proxy ARP nor does it allow the specified interface to override the route lookup for a packet.

See additional guidelines about mapped IP addresses in [Chapter 28, “Configuring Network Object NAT,”](#) and [Chapter 29, “Configuring Twice NAT.”](#)

## DNS and NAT

You might need to configure the adaptive security appliance to modify DNS replies by replacing the address in the reply with an address that matches the NAT configuration. You can configure DNS modification when you configure each translation.

This feature rewrites the A record, or address record, in DNS replies that match a NAT rule. For DNS replies traversing from a mapped interface to any other interface, the A record is rewritten from the mapped value to the real value. Inversely, for DNS replies traversing from any interface to a mapped interface, the A record is rewritten from the real value to the mapped value.

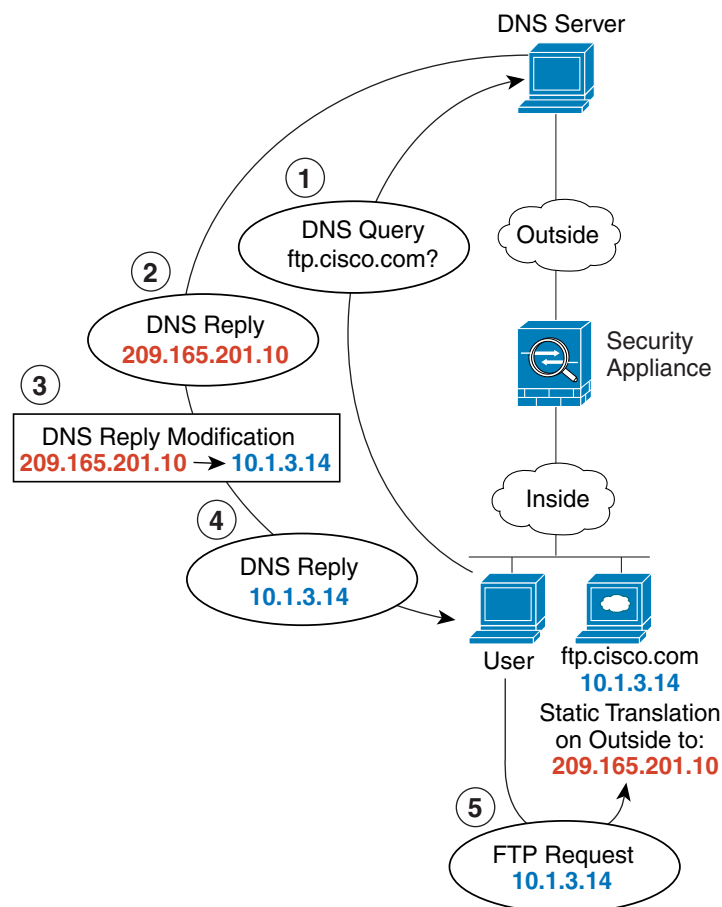

**Note**

If you configure a twice NAT rule, you cannot configure DNS modification if you specify the source address as well as the destination address. These kinds of rules can potentially have a different translation for a single address when going to A vs. B. Therefore, the adaptive security appliance cannot accurately match the IP address inside the DNS reply to the correct twice NAT rule; the DNS reply does not contain information about which source/destination address combination was in the packet that prompted the DNS request.

For example, a DNS server is accessible from the outside interface. A server, ftp.cisco.com, is on the inside interface. You configure the adaptive security appliance to statically translate the ftp.cisco.com real address (10.1.3.14) to a mapped address (209.165.201.10) that is visible on the outside network. (See [Figure 27-18.](#)) In this case, you want to enable DNS reply modification on this static rule so that inside users who have access to ftp.cisco.com using the real address receive the real address from the DNS server, and not the mapped address.

When an inside host sends a DNS request for the address of ftp.cisco.com, the DNS server replies with the mapped address (209.165.201.10). The adaptive security appliance refers to the static rule for the inside server and translates the address inside the DNS reply to 10.1.3.14. If you do not enable DNS reply modification, then the inside host attempts to send traffic to 209.165.201.10 instead of accessing ftp.cisco.com directly.

**Figure 27-18 DNS Reply Modification**

130021

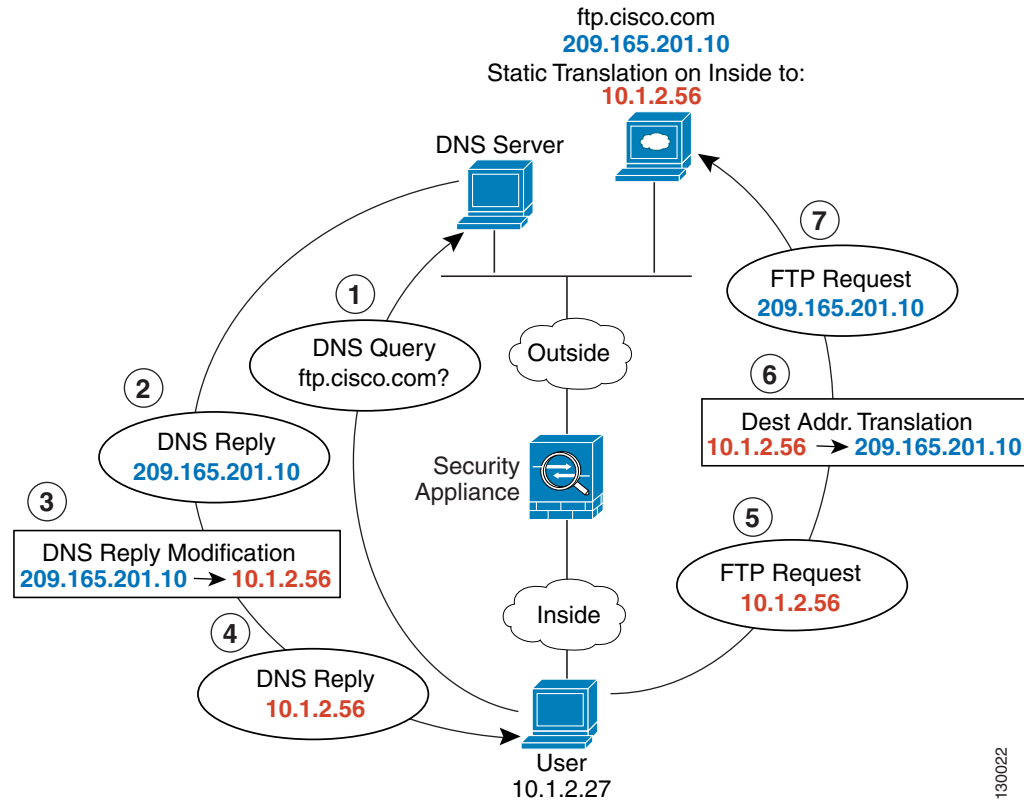

**Note**

If a user on a different network (for example, DMZ) also requests the IP address for ftp.cisco.com from the outside DNS server, then the IP address in the DNS reply is also modified for this user, even though the user is not on the Inside interface referenced by the static rule.

Figure 27-19 shows a web server and DNS server on the outside. The adaptive security appliance has a static translation for the outside server. In this case, when an inside user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.20.10. Because you want inside users to use the mapped address for ftp.cisco.com (10.1.2.56) you need to configure DNS reply modification for the static translation.

**Figure 27-19 DNS Reply Modification Using Outside NAT**

## Where to Go Next

To configure network object NAT, see [Chapter 28, “Configuring Network Object NAT.”](#)

To configure twice NAT, see [Chapter 29, “Configuring Twice NAT.”](#)

## CHAPTER 28

# Configuring Network Object NAT

All NAT rules that are configured as a parameter of a network object are considered to be *network object NAT* rules. Network object NAT is a quick and easy way to configure NAT for a network object, which can be a single IP address, a range of addresses, or a subnet. After you configure the network object, you can then identify the mapped address for that object.

This chapter describes how to configure network object NAT, and it includes the following sections:

- [Information About Network Object NAT, page 28-1](#)
- [Licensing Requirements for Network Object NAT, page 28-2](#)
- [Prerequisites for Network Object NAT, page 28-2](#)
- [Guidelines and Limitations, page 28-2](#)
- [Configuring Network Object NAT, page 28-3](#)
- [Monitoring Network Object NAT, page 28-11](#)
- [Configuration Examples for Network Object NAT, page 28-12](#)
- [Feature History for Network Object NAT, page 28-20](#)

**Note**

For detailed information about how NAT works, see [Chapter 27, “Information About NAT.”](#)

## Information About Network Object NAT

When a packet enters the adaptive security appliance, both the source and destination IP addresses are checked against the network object NAT rules. The source and destination address in the packet can be translated by separate rules if separate matches are made. These rules are not tied to each other; different combinations of rules can be used depending on the traffic.

Because the rules are never paired, you cannot specify that a source address should be translated to A when going to destination X, but be translated to B when going to destination Y. Use twice NAT for that kind of functionality (twice NAT lets you identify the source and destination address in a single rule).

For detailed information about the differences between twice NAT and network object NAT, see the [“How NAT is Implemented” section on page 27-15](#).

Network object NAT rules are added to section 2 of the NAT rules table. For more information about NAT ordering, see the [“NAT Rule Order” section on page 27-19](#).

# Licensing Requirements for Network Object NAT

The following table shows the licensing requirements for this feature:

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Prerequisites for Network Object NAT

Depending on the configuration, you can configure the mapped address inline if desired or you can create a network object or network object group for the mapped address (the **object network** or **object-group network** command). Network object groups are particularly useful for creating a mapped address pool with discontinuous IP address ranges or multiple hosts or subnets. To create a network object or group, see the [“Configuring Objects and Groups” section on page 11-1](#).

For specific guidelines for objects and groups, see the configuration section for the NAT type you want to configure. See also the [“Guidelines and Limitations”](#) section.

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

- Supported in routed and transparent firewall mode.
- In transparent mode, you must specify the real and mapped interfaces; you cannot use **any**.
- In transparent mode, you cannot configure interface PAT, because the transparent mode interfaces do not have IP addresses. You also cannot use the management IP address as a mapped address.

### IPv6 Guidelines

Does not support IPv6.

### Additional Guidelines

- You can only define a single NAT rule for a given object; if you want to configure multiple NAT rules, you need to create multiple objects that specify the same IP address, for example, **object network obj-10.10.10.1-01**, **object network obj-10.10.10.1-02**, and so on.

- If you change the NAT configuration, and you do not want to wait for existing translations to time out before the new NAT information is used, you can clear the translation table using the **clear xlate** command. However, clearing the translation table disconnects all current connections that use translations.

**Note**

If you remove a dynamic NAT or PAT rule, and then add a new rule with mapped addresses that overlap the addresses in the removed rule, then the new rule will not be used until all connections associated with the removed rule time out or are cleared using the **clear xlate** command. This safeguard ensures that the same address is not assigned to multiple hosts.

- Objects and object groups used in NAT cannot be undefined; they must include IP addresses.
- The mapped IP address pool cannot include:
  - The mapped interface IP address. If you specify **any** interface for the rule, then all interface IP addresses are disallowed. For interface PAT (routed mode only), use the **interface** keyword instead of the IP address.
  - (Transparent mode) The management IP address.
  - (Dynamic NAT) The standby interface IP address when VPN is enabled.
  - Existing VPN pool addresses.

## Configuring Network Object NAT

This section describes how to configure network object NAT to create rules for dynamic NAT, dynamic PAT, static NAT, static NAT with port translation, and identity NAT. This section includes the following topics:

- [Configuring Dynamic NAT, page 28-4](#)
- [Configuring Dynamic PAT \(Hide\), page 28-6](#)
- [Configuring Static NAT or Static NAT with Port Translation, page 28-8](#)
- [Configuring Identity NAT, page 28-10](#)

# Configuring Dynamic NAT

This section describes how to configure a dynamic NAT rule using network object NAT. For more information, see the [“Dynamic NAT” section on page 27-8](#).

## Detailed Steps

|        | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p>Network object:</p> <pre>object network obj_name   range ip_address_1 ip_address_2</pre> <p>Network object group:</p> <pre>object-group network grp_name {network-object {object net_obj_name   host ip_address}   group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network TEST hostname(config-network-object)# range 10.1.1.1 10.1.1.70  hostname(config)# object network TEST2 hostname(config-network-object)# range 10.1.2.1 10.1.2.70  hostname(config-network-object)# object-group network MAPPED_IPS hostname(config-network)# network-object object TEST hostname(config-network)# network-object object TEST2 hostname(config-network)# network-object host 10.1.2.79</pre> | <p>To specify the mapped addresses (that you want to translate to), configure a network object or network object group. A network object group can contain objects and/or inline addresses.</p> <p><b>Note</b> The object or group cannot contain a subnet. You can share this mapped object across different dynamic NAT rules, if desired.</p> <p>See the <a href="#">“Guidelines and Limitations” section on page 28-2</a> for information about disallowed mapped IP addresses.</p> <p>For more information, see the <a href="#">“Configuring Objects” section on page 11-3</a>.</p> |
| Step 2 | <pre>object network obj_name</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network my-host-obj1</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <p>Configures a network object for which you want to configure NAT, or enters object network configuration mode for an existing network object.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|        | Command                                                                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <p><code>{host ip_address   subnet subnet_address netmask   range ip_address_1 ip_address_2}</code></p> <p><b>Example:</b></p> <pre>hostname(config-network-object)# subnet 10.1.1.0 255.255.255.0</pre>  | If you are creating a new network object, defines the real IP address(es) that you want to translate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 4 | <p><code>nat [(real_ifc,mapped_ifc)] dynamic mapped_obj [interface] [dns]</code></p> <p><b>Example:</b></p> <pre>hostname(config-network-object)# nat (inside,outside) dynamic MAPPED_IPS interface</pre> | <p>Configures dynamic NAT for the object IP addresses. See the following guidelines:</p> <ul style="list-style-type: none"> <li>• <b>Interfaces</b>—If you do not specify the real and mapped interfaces, all interfaces are used. You can also specify the keyword <b>any</b> for one or both of the interfaces. Be sure to include the parentheses in your command.</li> <li>• <b>Mapped IP address</b>—Specify the mapped IP address as: <ul style="list-style-type: none"> <li>– An existing network object (see <a href="#">Step 1</a>).</li> <li>– An existing network object group (see <a href="#">Step 1</a>).</li> </ul> </li> </ul> <p><b>Note</b> You can share this mapped object across different dynamic NAT rules, if desired.</p> <ul style="list-style-type: none"> <li>• <b>Interface PAT fallback</b>—If you specify a mapped object or group followed by the <b>interface</b> keyword, then the IP address of the mapped interface is only used if all of the other mapped addresses are already allocated. For this option, you must configure a specific interface for the <i>mapped_ifc</i>. (You cannot specify <b>interface</b> in transparent mode).</li> <li>• <b>DNS</b>—The <b>dns</b> keyword translates DNS replies. Be sure DNS inspection is enabled (it is enabled by default). See the “DNS and NAT” section on page 27-21 for more information.</li> </ul> <p><b>Note</b> You can only define a single NAT rule for a given object. See the “Additional Guidelines” section on page 28-2.</p> |

## Examples

The following example configures dynamic NAT that hides 192.168.2.0 network behind a range of outside addresses 10.2.2.1 through 10.2.2.10:

```
hostname(config)# object network my-range-obj
hostname(config-network-object)# range 10.2.2.1 10.2.2.10
hostname(config)# object network my-inside-net
hostname(config-network-object)# subnet 192.168.2.0 255.255.255.0
hostname(config-network-object)# nat (inside,outside) dynamic my-range-obj
```

The following example configures dynamic NAT with dynamic PAT backup. Hosts on inside network 10.76.11.0 are mapped first to the nat-range1 pool (10.10.10.10-10.10.10.20). After all addresses in the nat-range1 pool are allocated, dynamic PAT is performed using the pat-ip1 address (10.10.10.21). In the unlikely event that the PAT translations are also use up, dynamic PAT is performed using the outside interface address.

```
hostname(config)# object network nat-range1
hostname(config-network-object)# range 10.10.10.10 10.10.10.20
```

```
hostname(config-network-object)# object network pat-ip1
hostname(config-network-object)# host 10.10.10.21

hostname(config-network-object)# object-group network nat-pat-grp
hostname(config-network-object)# network-object object nat-range1
hostname(config-network-object)# network-object object pat-ip1

hostname(config-network-object)# object network my_net_obj5
hostname(config-network-object)# subnet 10.76.11.0 255.255.255.0
hostname(config-network-object)# nat (inside,outside) dynamic nat-pat-grp interface
```

## Configuring Dynamic PAT (Hide)

This section describes how to configure a dynamic PAT (hide) rule using network object NAT. For more information, see the [“Dynamic PAT” section on page 27-10](#).

### Detailed Steps

|        | Command                                                                                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|        | Step 2<br><br><b>object network</b> <i>obj_name</i><br><br><b>Example:</b><br>hostname(config)# object network my-host-obj1                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|        | Command                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <pre>{host ip_address   subnet subnet_address netmask   range ip_address_1 ip_address_2}</pre> <p><b>Example:</b></p> <pre>hostname(config-network-object)# range 10.1.1.1 10.1.1.90</pre>                   | If you are creating a new network object, defines the real IP address(es) that you want to translate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 4 | <pre>nat [(real_ifc,mapped_ifc)] dynamic {mapped_inline_host_ip   mapped_obj   interface} [dns]</pre> <p><b>Example:</b></p> <pre>hostname(config-network-object)# nat (any,outside) dynamic interface</pre> | <p>Configures dynamic PAT for the object IP addresses. See the following guidelines:</p> <ul style="list-style-type: none"> <li>• <b>Interfaces</b>—If you do not specify the real and mapped interfaces, all interfaces are used. You can also specify the keyword <b>any</b> for one or both of the interfaces. Be sure to include the parentheses in your command.</li> <li>• <b>Mapped IP address</b>—You can specify the mapped IP address as: <ul style="list-style-type: none"> <li>– An inline host address.</li> <li>– An existing network object that is defined as a host address (see <a href="#">Step 1</a>).</li> <li>– <b>interface</b>—(Routed mode only) The IP address of the mapped interface is used as the mapped address. For this option, you must configure a specific interface for the <i>mapped_ifc</i>. You must use this keyword when you want to use the interface IP address; you cannot enter it inline or as an object.</li> </ul> </li> </ul> <p><b>Note</b> You can share this mapped IP address across different dynamic PAT rules, if desired.</p> <ul style="list-style-type: none"> <li>• <b>DNS</b>—The <b>dns</b> keyword translates DNS replies. Be sure DNS inspection is enabled (it is enabled by default). See the “DNS and NAT” section on page 27-21 for more information.</li> </ul> <p><b>Note</b> You can only define a single NAT rule for a given object. See the “Additional Guidelines” section on page 28-2.</p> |

## Examples

The following example configures dynamic PAT that hides the 192.168.2.0 network behind address 10.2.2.2:

```
hostname(config)# object network my-inside-net
hostname(config-network-object)# subnet 192.168.2.0 255.255.255.0
hostname(config-network-object)# nat (inside,outside) dynamic 10.2.2.2
```

The following example configures dynamic PAT that hides the 192.168.2.0 network behind the outside interface address:

```
hostname(config)# object network my-inside-net
hostname(config-network-object)# subnet 192.168.2.0 255.255.255.0
hostname(config-network-object)# nat (inside,outside) dynamic interface
```

# Configuring Static NAT or Static NAT with Port Translation

This section describes how to configure a static NAT rule using network object NAT. For more information, see the [“Static NAT” section on page 27-3](#).

## Detailed Steps

|        | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p>(Optional)</p> <p>Network object:</p> <pre>object network obj_name   {host ip_address      subnet subnet_address netmask      range ip_address_1 ip_address_2}</pre> <p>Network object group:</p> <pre>object-group network grp_name   {network-object {object net_obj_name      subnet_address netmask      host ip_address}      group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network MAPPED_IPS hostname(config-network-object)# subnet 10.1.1.0 255.255.255.0</pre> | <p>To specify the mapped addresses (that you want to translate to), configure a network object or network object group. A network object group can contain objects and/or inline addresses.</p> <p>See the <a href="#">“Guidelines and Limitations” section on page 28-2</a> for information about disallowed mapped IP addresses.</p> <p>For more information, see the <a href="#">“Configuring Objects” section on page 11-3</a>.</p> |
| Step 2 | <pre>object network obj_name</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network my-host-obj1</pre>                                                                                                                                                                                                                                                                                                                                                                                                  | <p>Configures a network object for which you want to configure NAT, or enters object network configuration mode for an existing network object.</p>                                                                                                                                                                                                                                                                                     |

|        | Command                                                                                                                                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <pre>{host ip_address   subnet subnet_address netmask   range ip_address_1 ip_address_2}</pre> <p><b>Example:</b></p> <pre>hostname(config-network-object)# subnet 10.2.1.0 255.255.255.0</pre>                                                                           | <p>If you are creating a new network object, defines the real IP address(es) that you want to translate.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 4 | <pre>nat [(real_ifc,mapped_ifc)] static {mapped_inline_ip   mapped_obj   interface} [dns   service {tcp   udp} real_port mapped_port]</pre> <p><b>Example:</b></p> <pre>hostname(config-network-object)# nat (inside,outside) static MAPPED_IPS service tcp 80 8080</pre> | <p>Configures static NAT for the object IP addresses. See the following guidelines:</p> <ul style="list-style-type: none"> <li>• <b>Interfaces</b>—If you do not specify the real and mapped interfaces, all interfaces are used. You can also specify the keyword <b>any</b> for one or both of the interfaces. Be sure to include the parentheses in your command.</li> <li>• <b>Mapped IP Addresses</b>—You can specify the mapped IP address as: <ul style="list-style-type: none"> <li>– An inline IP address. The netmask or range for the mapped network is the same as that of the real network. For example, if the real network is a host, then this address will be a host address. In the case of a range, then the mapped addresses include the same number of addresses as the real range. For example, if the real address is defined as a range from 10.1.1.1 through 10.1.1.6, and you specify 172.20.1.1 as the mapped address, then the mapped range will include 172.20.1.1 through 172.20.1.6.</li> <li>– An existing network object (see <a href="#">Step 1</a>).</li> <li>– An existing network object group (see <a href="#">Step 1</a>).</li> <li>– <b>interface</b>—(Static NAT with port translation only) For this option, you must configure a specific interface for the <i>mapped_ifc</i>. Be sure to also configure the <b>service</b> keyword. (You cannot specify <b>interface</b> in transparent mode).</li> </ul> <p>Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses. For more information, see the “<a href="#">Static NAT</a>” section on page 27-3.</p> </li> <li>• <b>DNS</b>—The <b>dns</b> keyword translates DNS replies. Be sure DNS inspection is enabled (it is enabled by default). See the “<a href="#">DNS and NAT</a>” section on page 27-21 for more information. This option is not available if you specify the <b>service</b> keyword.</li> <li>• (Static NAT with port translation only) <b>Port translation</b>—Specify <b>tcp</b> or <b>udp</b> and the real and mapped ports. You can enter either a port number or a well-known port name (such as <b>ftp</b>).</li> </ul> <p><b>Note</b> You can only define a single NAT rule for a given object. See the “<a href="#">Additional Guidelines</a>” section on page 28-2.</p> |

## Examples

The following example configures static NAT for the real host 10.1.1.1 on the inside to 10.2.2.2 on the outside with DNS rewrite enabled.

```
hostname(config)# object network my-host-obj1
hostname(config-network-object)# host 10.1.1.1
hostname(config-network-object)# nat (inside,outside) static 10.2.2.2 dns
```

The following example configures static NAT for the real host 10.1.1.1 on the inside to 2.2.2.2 on the outside using a mapped object.

```
hostname(config)# object network my-mapped-obj
hostname(config-network-object)# host 10.2.2.2

hostname(config-network-object)# object network my-host-obj1
hostname(config-network-object)# host 10.1.1.1
hostname(config-network-object)# nat (inside,outside) static my-mapped-obj
```

The following example configures static NAT with port translation for 10.1.1.1 at TCP port 21 to the outside interface at port 2121.

```
hostname(config)# object network my-ftp-server
hostname(config-network-object)# host 10.1.1.1
hostname(config-network-object)# nat (inside,outside) static interface service tcp 21 2121
```

## Configuring Identity NAT

This section describes how to configure an identity NAT rule using network object NAT. For more information, see the [“Identity NAT” section on page 27-11](#).

### Detailed Steps

|        | Command                                                                                                                                                                                                                                                                                 | Purpose                                                                                                                                                                                                      |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p>(Optional)</p> <pre>object network obj_name {host ip_address    subnet subnet_address netmask    range ip_address_1 ip_address_2}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network MAPPED_IPS hostname(config-network-object)# subnet 10.1.1.0 255.255.255.0</pre> | <p>For the mapped addresses (which will be the same as the real addresses), configure a network object.</p> <p>For more information, see the <a href="#">“Configuring Objects” section on page 11-3</a>.</p> |
| Step 2 | <pre>object network obj_name</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network my-host-obj1</pre>                                                                                                                                                                      | <p>Configures a network object for which you want to perform identity NAT, or enters object network configuration mode for an existing network object.</p>                                                   |

|        | Command                                                                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <pre>{host ip_address   subnet subnet_address netmask   range ip_address_1 ip_address_2}</pre> <p><b>Example:</b></p> <pre>hostname(config-network-object)# subnet 10.1.1.0 255.255.255.0</pre> | If you are creating a new network object, defines the real IP address(es) to which you want to perform identity NAT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Step 4 | <pre>nat [(real_ifc,mapped_ifc)] static {mapped_inline_ip   mapped_obj}</pre> <p><b>Example:</b></p> <pre>hostname(config-network-object)# nat (inside,outside) static MAPPED_IPS</pre>         | <p>Configures identity NAT for the object IP addresses. See the following guidelines:</p> <ul style="list-style-type: none"> <li>• If you do not specify the real and mapped interfaces, all interfaces are used. You can also specify the keyword <b>any</b> for one or both of the interfaces. Be sure to include the parentheses in your command.</li> <li>• Be sure to configure the same IP address for both the mapped and real address. Typically, you will enter the address as an inline address, but you can create a second network object with the same IP address defined and use that object (see <a href="#">Step 1</a>).</li> </ul> <p><b>Note</b> You can only define a single NAT rule for a given object. See the <a href="#">“Additional Guidelines” section on page 28-2</a>.</p> |

## Example

The following example maps a host address to itself using an inline mapped address:

```
hostname(config)# object network my-host-obj1
hostname(config-network-object)# host 10.1.1.1
hostname(config-network-object)# nat (inside,outside) static 10.1.1.1
```

The following example maps a host address to itself using a network object:

```
hostname(config)# object network my-host-obj1-identity
hostname(config-network-object)# host 10.1.1.1

hostname(config-network-object)# object network my-host-obj1
hostname(config-network-object)# host 10.1.1.1
hostname(config-network-object)# nat (inside,outside) static my-host-obj1-identity
```

# Monitoring Network Object NAT

To monitor object NAT, enter one of the following commands:

| Command                    | Purpose                                                                                                         |
|----------------------------|-----------------------------------------------------------------------------------------------------------------|
| <code>show nat</code>      | Shows NAT statistics, including hits for each NAT rule.                                                         |
| <code>show nat pool</code> | Shows NAT pool statistics, including the addresses and ports allocated, and how many times they were allocated. |

| Command                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>show running-config nat</code> | <p>Shows the NAT configuration.</p> <p><b>Note</b> You cannot view the NAT configuration using the <b>show running-config object</b> command. You cannot reference objects or object groups that have not yet been created in <b>nat</b> commands. To avoid forward or circular references in <b>show</b> command output, the <b>show running-config</b> command shows the <b>object</b> command two times: first, where the IP address(es) are defined; and later, where the <b>nat</b> command is defined. This command output guarantees that objects are defined first, then object groups, and finally NAT. For example:</p> <pre> hostname# show running-config ... object network obj1   range 192.168.49.1 192.150.49.100 object network obj2   object 192.168.49.100 object network network-1   subnet &lt;network-1&gt; object network network-2   subnet &lt;network-2&gt; object-group network pool   network-object object obj1   network-object object obj2 ... object network network-1   nat (inside,outside) dynamic pool object network network-2   nat (inside,outside) dynamic pool </pre> |
| <code>show xlate</code>              | Shows current NAT session information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Configuration Examples for Network Object NAT

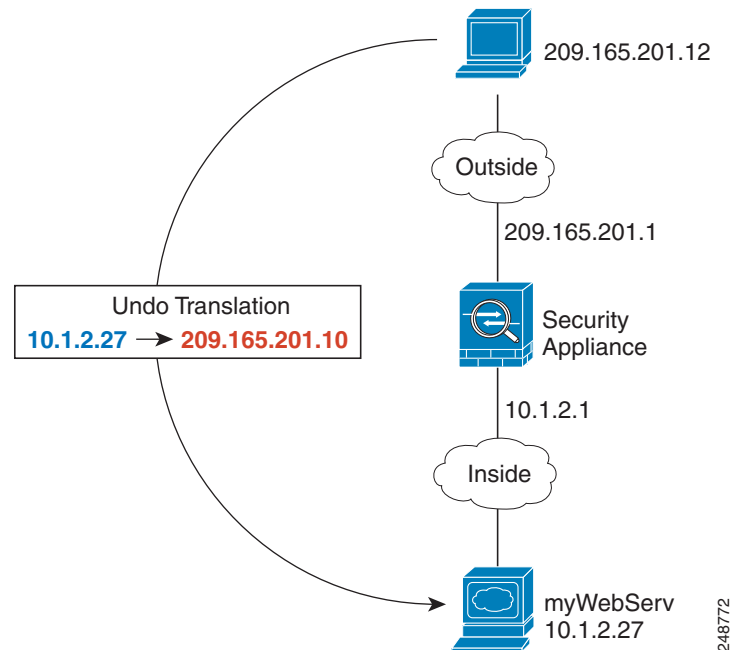

This section includes the following configuration examples:

- [Providing Access to an Inside Web Server \(Static NAT\), page 28-13](#)
- [NAT for Inside Hosts \(Dynamic NAT\) and NAT for an Outside Web Server \(Static NAT\), page 28-13](#)
- [Inside Load Balancer with Multiple Mapped Addresses \(Static NAT, One-to-Many\), page 28-15](#)
- [Single Address for FTP, HTTP, and SMTP \(Static NAT with Port Translation\), page 28-16](#)
- [DNS Server on Mapped Interface, Web Server on Real Interface \(Static NAT with DNS Modification\), page 28-17](#)
- [DNS Server and Web Server on Mapped Interface, Web Server is Translated \(Static NAT with DNS Modification\), page 28-19](#)

## Providing Access to an Inside Web Server (Static NAT)

The following example performs static NAT for an inside web server. The real address is on a private network, so a public address is required. Static NAT is necessary so hosts can initiate traffic to the web server at a fixed address. (See [Figure 28-1](#)).

**Figure 28-1** Static NAT for an Inside Web Server

**Step 1** Create a network object for the internal web server:

```
hostname(config)# object network myWebServ
```

**Step 2** Define the web server address:

```
hostname(config-network-object)# host 10.1.2.27
```

**Step 3** Configure static NAT for the object:

```
hostname(config-network-object)# nat (inside,outside) static 209.165.201.10
```

## NAT for Inside Hosts (Dynamic NAT) and NAT for an Outside Web Server (Static NAT)

The following example configures dynamic NAT for inside users on a private network when they access the outside. Also, when inside users connect to an outside web server, that web server address is translated to an address that appears to be on the inside network. (See [Figure 28-2](#)).

**Figure 28-2** Dynamic NAT for Inside, Static NAT for Outside Web Server

**Step 1** Create a network object for the dynamic NAT pool to which you want to translate the inside addresses:

```
hostname(config)# object network myNatPool
hostname(config-network-object)# range 209.165.201.20 209.165.201.30
```

**Step 2** Create a network object for the inside network:

```
hostname(config)# object network myInsNet
hostname(config-network-object)# subnet 10.1.2.0 255.255.255.0
```

**Step 3** Enable dynamic NAT for the inside network:

```
hostname(config-network-object)# nat (inside,outside) dynamic myNatPool
```

**Step 4** Create a network object for the outside web server:

```
hostname(config)# object network myWebServ
```

**Step 5** Define the web server address:

```
hostname(config-network-object)# host 209.165.201.12
```

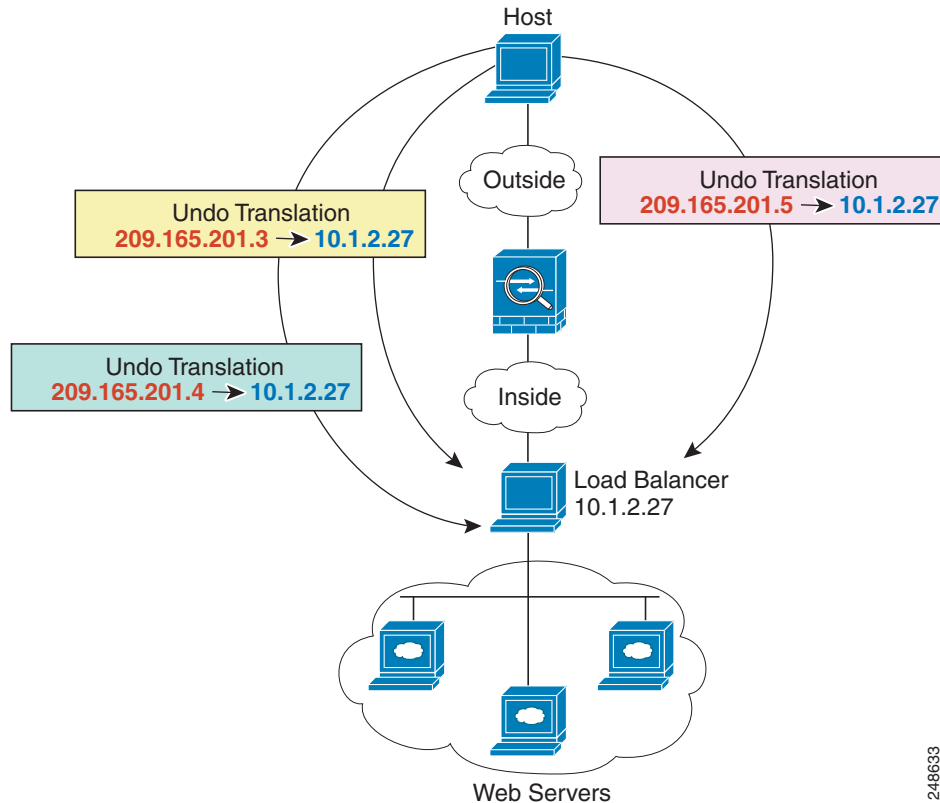

**Step 6** Configure static NAT for the web server:

```
hostname(config-network-object)# nat (outside,inside) static 10.1.2.20
```

## Inside Load Balancer with Multiple Mapped Addresses (Static NAT, One-to-Many)

The following example shows an inside load balancer that is translated to multiple IP addresses. When an outside host accesses one of the mapped IP addresses, it is untranslated to the single load balancer address. Depending on the URL requested, it redirects traffic to the correct web server. (See [Figure 28-3](#)).

**Figure 28-3** Static NAT with One-to-Many for an Inside Load Balancer

**Step 1** Create a network object for the addresses to which you want to map the load balancer:

```
hostname(config)# object network myPublicIPs
hostname(config-network-object)# range 209.165.201.3 209.265.201.8
```

**Step 2** Create a network object for the load balancer:

```
hostname(config)# object network myLBHost
```

**Step 3** Define the load balancer address:

```
hostname(config-network-object)# host 10.1.2.27
```

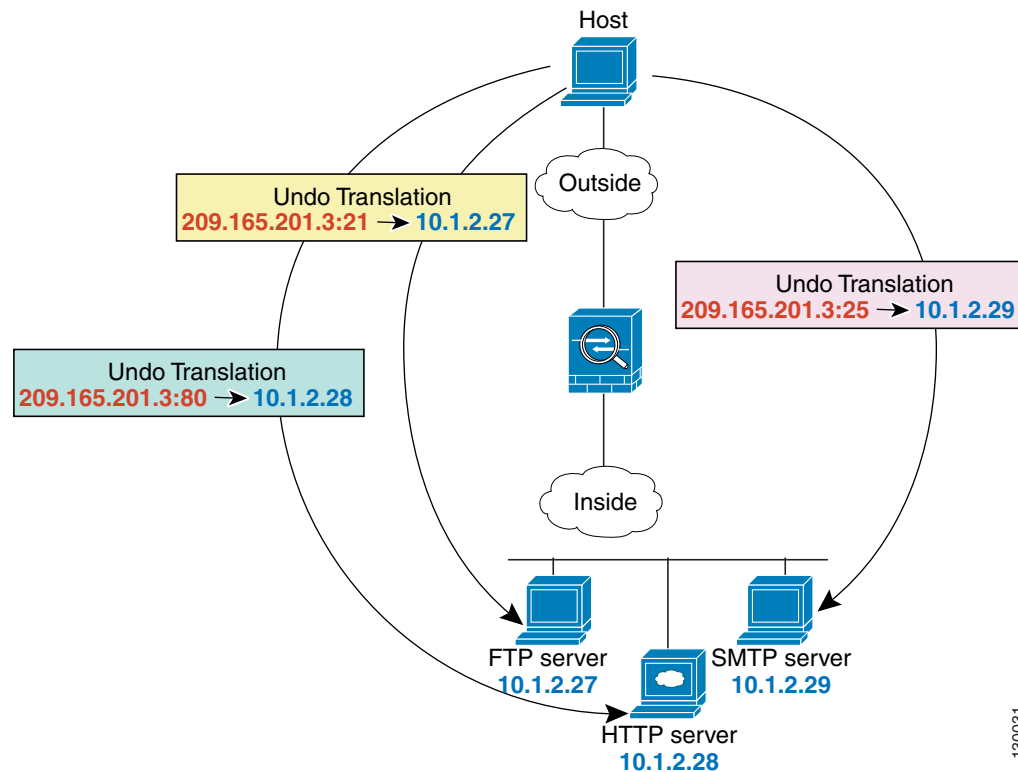

**Step 4** Configure static NAT for the load balancer:

```
hostname(config-network-object)# nat (inside,outside) static myPublicIPs
```

## Single Address for FTP, HTTP, and SMTP (Static NAT with Port Translation)

The following static NAT with port translation example provides a single address for remote users to access FTP, HTTP, and SMTP. These servers are actually different devices on the real network, but for each server, you can specify static NAT with port translation rules that use the same mapped IP address, but different ports. (See [Figure 28-4](#).)

**Figure 28-4** Static NAT with Port Translation

**Step 1** Create a network object for the FTP server address:

```
hostname(config)# object network FTP_SERVER
```

**Step 2** Define the FTP server address, and configure static NAT with identity port translation for the FTP server:

```
hostname(config-network-object)# host 10.1.2.27
hostname(config-network-object)# nat (inside,outside) static 209.165.201.3 service tcp ftp ftp
```

**Step 3** Create a network object for the HTTP server address:

```
hostname(config)# object network HTTP_SERVER
```

**Step 4** Define the HTTP server address, and configure static NAT with identity port translation for the HTTP server:

```
hostname(config-network-object)# host 10.1.2.28
hostname(config-network-object)# nat (inside,outside) static 209.165.201.3 service tcp http http
```

**Step 5** Create a network object for the SMTP server address:

```
hostname(config)# object network SMTP_SERVER
```

**Step 6** Define the SMTP server address, and configure static NAT with identity port translation for the SMTP server:

```
hostname(config-network-object)# host 10.1.2.29
hostname(config-network-object)# nat (inside,outside) static 209.165.201.3 service tcp
smtp smtp
```

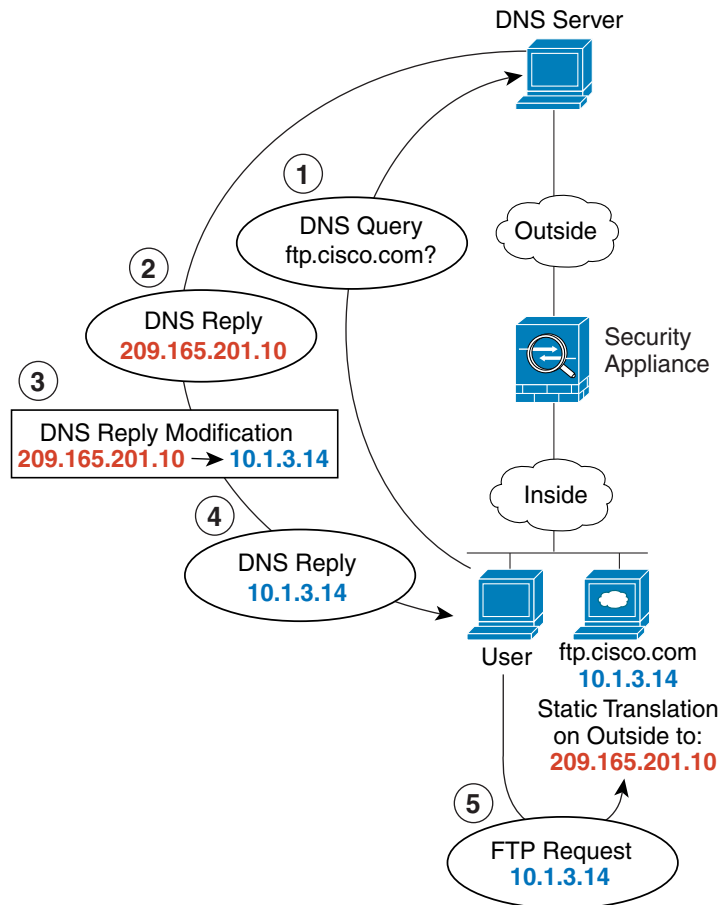

---

## DNS Server on Mapped Interface, Web Server on Real Interface (Static NAT with DNS Modification)

For example, a DNS server is accessible from the outside interface. A server, ftp.cisco.com, is on the inside interface. You configure the adaptive security appliance to statically translate the ftp.cisco.com real address (10.1.3.14) to a mapped address (209.165.201.10) that is visible on the outside network. (See [Figure 28-5](#).) In this case, you want to enable DNS reply modification on this static rule so that inside users who have access to ftp.cisco.com using the real address receive the real address from the DNS server, and not the mapped address.

When an inside host sends a DNS request for the address of ftp.cisco.com, the DNS server replies with the mapped address (209.165.201.10). The adaptive security appliance refers to the static rule for the inside server and translates the address inside the DNS reply to 10.1.3.14. If you do not enable DNS reply modification, then the inside host attempts to send traffic to 209.165.201.10 instead of accessing ftp.cisco.com directly.

**Figure 28-5 DNS Reply Modification**

130021

**Step 1** Create a network object for the FTP server address:

```
hostname(config)# object network FTP_SERVER
```

**Step 2** Define the FTP server address, and configure static NAT with DNS modification:

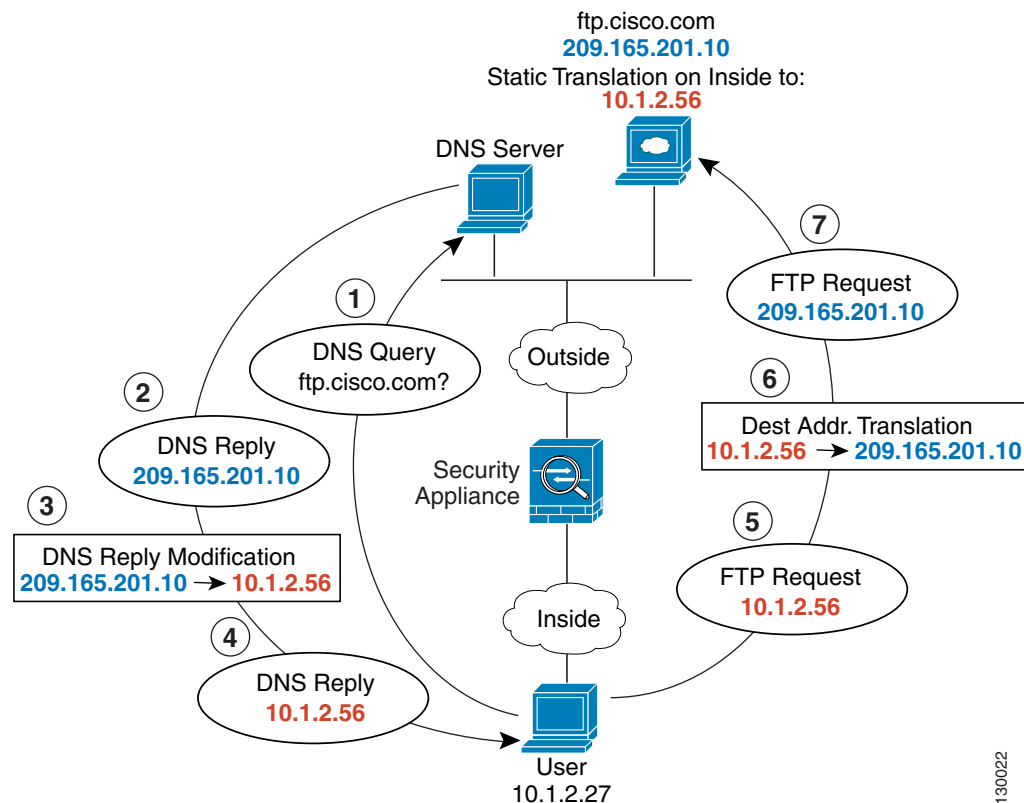

```
hostname(config-network-object)# host 10.1.3.14
hostname(config-network-object)# nat (inside,outside) static 209.165.201.10 dns
```

## DNS Server and Web Server on Mapped Interface, Web Server is Translated (Static NAT with DNS Modification)

Figure 28-6 shows a web server and DNS server on the outside. The adaptive security appliance has a static translation for the outside server. In this case, when an inside user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.20.10. Because you want inside users to use the mapped address for ftp.cisco.com (10.1.2.56) you need to configure DNS reply modification for the static translation.

Figure 28-6 DNS Reply Modification Using Outside NAT

**Step 1** Create a network object for the FTP server address:

```
hostname(config)# object network FTP_SERVER
```

**Step 2** Define the FTP server address, and configure static NAT with DNS modification:

```
hostname(config-network-object)# host 209.165.20.10
hostname(config-network-object)# nat (outside,inside) static 10.1.2.56 dns
```

# Feature History for Network Object NAT

Table 28-1 lists each feature change and the platform release in which it was implemented.

Table 28-1      Feature History for Network Object NAT

| Feature Name       | Platform Releases | Feature Information                                                                                                                                                                                                     |

# CHAPTER 29

## Configuring Twice NAT

Twice NAT lets you identify both the source and destination address in a single rule. This chapter shows you how to configure twice NAT and includes the following sections:

- [Information About Twice NAT, page 29-1](#)
- [Licensing Requirements for Twice NAT, page 29-2](#)
- [Prerequisites for Twice NAT, page 29-2](#)
- [Guidelines and Limitations, page 29-2](#)
- [Configuring Twice NAT, page 29-3](#)
- [Monitoring Twice NAT, page 29-20](#)
- [Configuration Examples for Twice NAT, page 29-20](#)
- [Feature History for Twice NAT, page 29-23](#)

### Note

For detailed information about how NAT works, see [Chapter 27, “Information About NAT.”](#)

## Information About Twice NAT

Twice NAT lets you identify both the source and destination address in a single rule. Specifying both the source and destination addresses lets you specify that a source address should be translated to A when going to destination X, but be translated to B when going to destination Y, for example.

### Note

For static NAT, the rule is bidirectional, so be aware that “source” and “destination” are used in commands and descriptions throughout this guide even though a given connection might originate at the “destination” address. For example, if you configure static NAT with port address translation, and specify the source address as a Telnet server, and you want all traffic going to that Telnet server to have the port translated from 2323 to 23, then in the command, you must specify the *source* ports to be translated (real: 23, mapped: 2323). You specify the source ports because you specified the Telnet server address as the source address.

The destination address is optional. If you specify the destination address, you can either map it to itself (identity NAT), or you can map it to a different address. The destination mapping is always a static mapping.

Twice NAT also lets you use service objects for static NAT with port translation; network object NAT only accepts inline definition.

For detailed information about the differences between twice NAT and network object NAT, see the [“How NAT is Implemented” section on page 27-15](#).

Twice NAT rules are added to section 1 of the NAT rules table, or if specified, section 3. For more information about NAT ordering, see the [“NAT Rule Order” section on page 27-19](#).

## Licensing Requirements for Twice NAT

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Prerequisites for Twice NAT

- For both the real and mapped addresses, configure network objects or network object groups (the **object network** or **object-group network** command). Network object groups are particularly useful for creating a mapped address pool with discontinuous IP address ranges or multiple hosts or subnets. To create a network object or group, see the [“Configuring Objects and Groups” section on page 11-1](#).
- For static NAT with port translation, configure TCP or UDP service objects (the **object service** command). To create a service object, see the [“Configuring a Service Object” section on page 11-4](#).

For specific guidelines for objects and groups, see the configuration section for the NAT type you want to configure. See also the [“Guidelines and Limitations” section](#).

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

- Supported in routed and transparent firewall mode.
- In transparent mode, you must specify the real and mapped interfaces; you cannot use **any**.
- In transparent mode, you cannot configure interface PAT, because the transparent mode interfaces do not have IP addresses. You also cannot use the management IP address as a mapped address.

### IPv6 Guidelines

Does not support IPv6.

**Additional Guidelines**

- If you change the NAT configuration, and you do not want to wait for existing translations to time out before the new NAT information is used, you can clear the translation table using the **clear xlate** command. However, clearing the translation table disconnects all current connections that use translations.

**Note** If you remove a dynamic NAT or PAT rule, and then add a new rule with mapped addresses that overlap the addresses in the removed rule, then the new rule will not be used until all connections associated with the removed rule time out or are cleared using the **clear xlate** command. This safeguard ensures that the same address is not assigned to multiple hosts.

- Objects and object groups used in NAT cannot be undefined; they must include IP addresses.
- The mapped IP address pool cannot include:
  - The mapped interface IP address. If you specify **any** interface for the rule, then all interface IP addresses are disallowed. For interface PAT (routed mode only), use the **interface** keyword instead of the IP address.
  - (Transparent mode) The management IP address.
  - (Dynamic NAT) The standby interface IP address when VPN is enabled.
  - Existing VPN pool addresses.

## Configuring Twice NAT

This section describes how to configure twice NAT to create rules for dynamic NAT, dynamic PAT, static NAT, static NAT with port translation, and identity NAT. This section includes the following topics:

- [Configuring Dynamic NAT, page 29-3](#)
- [Configuring Dynamic PAT \(Hide\), page 29-8](#)
- [Configuring Static NAT or Static NAT with Port Translation, page 29-12](#)
- [Configuring Identity NAT, page 29-17](#)

## Configuring Dynamic NAT

This section describes how to configure a dynamic NAT rule using twice NAT. For more information about dynamic NAT, see the [“Dynamic NAT” section on page 27-8](#).

## Detailed Steps

|        | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p>Network object:</p> <pre>object network obj_name {host ip_address   subnet subnet_address netmask   range ip_address_1 ip_address_2}</pre> <p>Network object group:</p> <pre>object-group network grp_name {network-object {object net_obj_name   subnet_address netmask   host ip_address}   group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network MyInsNet hostname(config-network-object)# subnet 10.1.1.0 255.255.255.0</pre> | <p>Configure the real source addresses.</p> <p>You can configure either a network object or a network object group. For more information, see the <a href="#">“Configuring Objects” section on page 11-3</a>.</p> <p>If you want to translate all traffic, you can specify the <b>any</b> keyword instead of creating an object or group; skip this step.</p>                                                                                                                                                                                    |
|        | <p>Network object:</p> <pre>object network obj_name range ip_address_1 ip_address_2</pre> <p>Network object group:</p> <pre>object-group network grp_name {network-object {object net_obj_name   host ip_address}   group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network NAT_POOL hostname(config-network-object)# range 209.165.201.10 209.165.201.20</pre>                                                                        | <p>Configure the mapped source addresses.</p> <p>You can configure either a network object or a network object group.</p> <p>For dynamic NAT, you typically configure a larger group of addresses to be mapped to a smaller group.</p> <p><b>Note</b> The mapped object or group cannot contain a subnet.</p> <p>You can share this mapped IP address across different dynamic NAT rules, if desired.</p> <p>See the <a href="#">“Guidelines and Limitations” section on page 29-2</a> for information about disallowed mapped IP addresses.</p> |

|               | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <p>(Optional)</p> <p>Network object:</p> <pre>object network obj_name   {host ip_address   subnet   subnet_address netmask   range   ip_address_1 ip_address_2}</pre> <p>Network object group:</p> <pre>object-group network grp_name   {network-object {object net_obj_name     subnet_address netmask     host ip_address}     group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network Server1 hostname(config-network-object)# host 209.165.201.8</pre>    | <p>Configure the real destination addresses.</p> <p>You can configure either a network object or a network object group.</p> <p>Although the main feature of twice NAT is the inclusion of the destination IP address, the destination address is optional. If you do specify the destination address, you can configure static translation for that address or just use identity NAT for it. You might want to configure twice NAT without a destination address to take advantage of some of the other qualities of twice NAT, including the use of network object groups for real addresses, or manually ordering of rules. For more information, see the <a href="#">“Main Differences Between Network Object NAT and Twice NAT”</a> section on page 27-15.</p>                                                                                                                                                                                                                                                                                                          |
| <b>Step 4</b> | <p>(Optional)</p> <p>Network object:</p> <pre>object network obj_name   {host ip_address   subnet   subnet_address netmask   range   ip_address_1 ip_address_2}</pre> <p>Network object group:</p> <pre>object-group network grp_name   {network-object {object net_obj_name     subnet_address netmask     host ip_address}     group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network Server1_mapped hostname(config-network-object)# host 10.1.1.67</pre> | <p>Configure the mapped destination addresses.</p> <p>You can configure either a network object or a network object group.</p> <p>The destination translation is always static. For identity NAT, simply use the same object or group for both the real and mapped addresses, and skip this step.</p> <p>If you want to translate the destination address, then the static mapping is typically one-to-one, so the real addresses have the same quantity as the mapped addresses. You can, however, have different quantities if desired. For more information, see the <a href="#">“Static NAT”</a> section on page 27-3.</p> <p>For static interface NAT with port translation, you can specify the <b>interface</b> keyword instead of a network object/group for the mapped address; you can skip this step. For more information, see the <a href="#">“Static Interface NAT with Port Translation”</a> section on page 27-5.</p> <p>See the <a href="#">“Guidelines and Limitations”</a> section on page 29-2 for information about disallowed mapped IP addresses.</p> |

| Command                                                                                                                                                                                                                                                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>Step 5</b> (Optional)</p> <pre>object service obj_name   service {tcp   udp} destination   operator port</pre> <p><b>Example:</b></p> <pre>hostname(config)# object service REAL_SVC hostname(config-service-object)# service tcp destination eq 80</pre> <pre>hostname(config)# object service MAPPED_SVC hostname(config-service-object)# service tcp destination eq 8080</pre> | <p>Configure service objects for:</p> <ul style="list-style-type: none"> <li>• Destination real TCP or UDP port</li> <li>• Destination mapped TCP or UDP port</li> </ul> <p>Dynamic NAT does not support port translation. However, because the <i>destination</i> translation is always static, you can perform port translation for the destination port. A service object can contain both a source and destination port, but only the destination port is used in this case. If you specify the source port, it will be ignored. NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports. The “not equal” (<b>neq</b>) operator is not supported.</p> |

|        | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 6 | <p><b>nat</b> [(<i>real_ifc</i>,<i>mapped_ifc</i>)] [<i>line</i>   {<b>after-auto</b> [<i>line</i>]}] <b>source dynamic</b> {<i>real_obj</i>   <b>any</b>} {<i>mapped_obj</i> [<b>interface</b>]} [<b>destination static</b> {<i>mapped_obj</i>   <b>interface</b>} <i>real_obj</i>] [<b>service</b> <i>mapped_dest_svc_obj</i> <i>real_dest_svc_obj</i>] [<b>dns</b>] [<b>inactive</b>] [<b>description</b> <i>desc</i>]</p> <p><b>Example:</b></p> <pre>hostname(config)# nat (inside,outside) source dynamic MyInsNet NAT_POOL destination static Server1_mapped Server1 service MAPPED_SVC REAL_SVC</pre> | <p>Configures dynamic NAT. See the following guidelines:</p> <ul style="list-style-type: none"> <li>• <b>Interfaces</b>—If you do not specify the real and mapped interfaces, all interfaces are used. You can also specify the keyword <b>any</b> for one or both of the interfaces.</li> <li>• <b>Line</b>—By default, the NAT rule is added to the end of section 1 of the NAT table (see the <a href="#">“NAT Rule Order” section on page 27-19</a>). If you want to add the rule into section 3 instead (after the network object NAT rules), then use the <b>after-auto</b> keyword. You can insert a rule anywhere in the applicable section using the <i>line</i> argument.</li> <li>• <b>Source addresses:</b> <ul style="list-style-type: none"> <li>– <b>Real</b>—Specify a network object, group, or the <b>any</b> keyword (see <a href="#">Step 1</a>). Use the <b>any</b> keyword if you want to translate all traffic from the real interface to the mapped interface.</li> <li>– <b>Mapped</b>—Specify a different network object or group (see <a href="#">Step 2</a>). You can share this mapped object across different dynamic NAT rules, if desired. If you specify a mapped object or group followed by the <b>interface</b> keyword (routed mode only), then the IP address of the mapped interface is only used if all other mapped addresses are already allocated. For this option, you must configure a specific interface for the <i>mapped_ifc</i>.</li> </ul> </li> <li>• <b>Destination addresses:</b> <ul style="list-style-type: none"> <li>– <b>Mapped</b>—Specify a network object or group, or for static interface NAT with port translation only, specify the <b>interface</b> keyword (see <a href="#">Step 4</a>). If you specify <b>interface</b>, be sure to also configure the <b>service</b> keyword. For this option, you must configure a specific interface for the <i>real_ifc</i>. See the <a href="#">“Static Interface NAT with Port Translation” section on page 27-5</a> for more information.</li> <li>– <b>Real</b>—Specify a network object or group (see <a href="#">Step 3</a>). For identity NAT, simply use the same object or group for both the real and mapped addresses.</li> </ul> </li> <li>• <b>Destination port</b>—Specify the <b>service</b> keyword along with the mapped and real service objects (see <a href="#">Step 5</a>). For identity port translation, simply use the same service object for both the real and mapped ports.</li> <li>• <b>(For a source-only rule) DNS</b>—The <b>dns</b> keyword translates DNS replies. Be sure DNS inspection is enabled (it is enabled by default). You cannot configure the <b>dns</b> keyword if you configure a <b>destination</b> address. See the <a href="#">“DNS and NAT” section on page 27-21</a> for more information.</li> <li>• <b>Inactive</b>—To make this rule inactive without having to remove the command, use the <b>inactive</b> keyword. To reactivate it, reenter the whole command without the <b>inactive</b> keyword.</li> <li>• <b>Description</b>—Provide a description up to 200 characters using the <b>description</b> keyword.</li> </ul> |

## Configuring Dynamic PAT (Hide)

This section describes how to configure a dynamic PAT (hide) rule using twice NAT. For more information about dynamic PAT, see the [“Dynamic PAT” section on page 27-10](#).

### Detailed Steps

|        | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p>Network object:</p> <pre>object network obj_name   {host ip_address   subnet   subnet_address netmask   range   ip_address_1 ip_address_2}</pre> <p>Network object group:</p> <pre>object-group network grp_name   {network-object {object net_obj_name     subnet_address netmask     host ip_address}     group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network MyInsNet hostname(config-network-object)# subnet 10.1.1.0 255.255.255.0</pre> | <p>Configure the real source addresses.</p> <p>You can configure either a network object or a network object group. For more information, see the <a href="#">“Configuring Objects” section on page 11-3</a>.</p> <p>If you want to translate all traffic, you can specify the <b>any</b> keyword instead of creating an object or group; skip this step.</p>                                                                                                                                                                                                                                                                                                                                                                |
| Step 2 | <pre>object network obj_name   host ip_address</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network PAT_IP hostname(config-network-object)# host 209.165.201.10</pre>                                                                                                                                                                                                                                                                                                        | <p>Configure the mapped source address.</p> <p>You can configure a network object.</p> <p>For dynamic PAT, configure a group of addresses to be mapped to a single address. You can either translate the real addresses to a single mapped address of your choosing, or you can translate them to the mapped interface address. If you want to use the interface address, do not configure a network object for the mapped address; instead use the <b>interface</b> keyword.</p> <p><b>Note</b> You can share this mapped object across different dynamic PAT rules, if desired.</p> <p>See the <a href="#">“Guidelines and Limitations” section on page 29-2</a> for information about disallowed mapped IP addresses.</p> |

|               | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <p>(Optional)</p> <p>Network object:</p> <pre>object network obj_name   {host ip_address   subnet   subnet_address netmask   range   ip_address_1 ip_address_2}</pre> <p>Network object group:</p> <pre>object-group network grp_name   {network-object {object net_obj_name     subnet_address netmask     host ip_address}     group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network Server1 hostname(config-network-object)# host 209.165.201.8</pre>    | <p>Configure the real destination addresses.</p> <p>You can configure either a network object or a network object group.</p> <p>Although the main feature of twice NAT is the inclusion of the destination IP address, the destination address is optional. If you do specify the destination address, you can configure static translation for that address or just use identity NAT for it. You might want to configure twice NAT without a destination address to take advantage of some of the other qualities of twice NAT, including the use of network object groups for real addresses, or manually ordering of rules. For more information, see the <a href="#">“Main Differences Between Network Object NAT and Twice NAT”</a> section on page 27-15.</p>                                                                                                                                                                                                                                                                                                          |
| <b>Step 4</b> | <p>(Optional)</p> <p>Network object:</p> <pre>object network obj_name   {host ip_address   subnet   subnet_address netmask   range   ip_address_1 ip_address_2}</pre> <p>Network object group:</p> <pre>object-group network grp_name   {network-object {object net_obj_name     subnet_address netmask     host ip_address}     group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network Server1_mapped hostname(config-network-object)# host 10.1.1.67</pre> | <p>Configure the mapped destination addresses.</p> <p>You can configure either a network object or a network object group.</p> <p>The destination translation is always static. For identity NAT, simply use the same object or group for both the real and mapped addresses, and skip this step.</p> <p>If you want to translate the destination address, then the static mapping is typically one-to-one, so the real addresses have the same quantity as the mapped addresses. You can, however, have different quantities if desired. For more information, see the <a href="#">“Static NAT”</a> section on page 27-3.</p> <p>For static interface NAT with port translation, you can specify the <b>interface</b> keyword instead of a network object/group for the mapped address; you can skip this step. For more information, see the <a href="#">“Static Interface NAT with Port Translation”</a> section on page 27-5.</p> <p>See the <a href="#">“Guidelines and Limitations”</a> section on page 29-2 for information about disallowed mapped IP addresses.</p> |

|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>Step 5</b> (Optional)</p> <pre>object service obj_name   service {tcp   udp} destination   operator port</pre> <p><b>Example:</b></p> <pre>hostname(config)# object service REAL_SVC hostname(config-service-object)# service tcp destination eq 80</pre> <pre>hostname(config)# object service MAPPED_SVC hostname(config-service-object)# service tcp destination eq 8080</pre> | <p>Configure service objects for:</p> <ul style="list-style-type: none"> <li>• Destination real TCP or UDP port</li> <li>• Destination mapped TCP or UDP port</li> </ul> <p>Dynamic PAT does not support additional port translation. However, because the <i>destination</i> translation is always static, you can perform port translation for the destination port. A service object can contain both a source and destination port, but only the destination port is used in this case. If you specify the source port, it will be ignored. NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports. The “not equal” (<b>neq</b>) operator is not supported.</p> |

| Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>Step 6</b></p> <pre> <b>nat</b> [(<i>real_ifc</i>,<i>mapped_ifc</i>)] [<i>line</i>   {<b>after-auto</b> [<i>line</i>]}] <b>source dynamic</b> {<i>real_obj</i>   <b>any</b>} {<i>mapped_obj</i>   <b>interface</b>} [<b>destination static</b> {<i>mapped_obj</i>   <b>interface</b>} <i>real_obj</i>] [<b>service</b> <i>mapped_dest_svc_obj</i> <i>real_dest_svc_obj</i>] [<b>dns</b>] [<b>inactive</b>] [<b>description</b> <i>desc</i>] </pre> <p><b>Example:</b></p> <pre> hostname(config)# nat (inside,outside) source dynamic MyInsNet interface destination static Server1 Server1 description Interface PAT for inside addresses when going to server 1 </pre> | <p>Configures dynamic PAT (hide). See the following guidelines:</p> <ul style="list-style-type: none"> <li>• <b>Interfaces</b>—If you do not specify the real and mapped interfaces, all interfaces are used. You can also specify the keyword <b>any</b> for one or both of the interfaces.</li> <li>• <b>Line</b>—By default, the NAT rule is added to the end of section 1 of the NAT table (see the “<a href="#">NAT Rule Order</a>” section on page 27-19). If you want to add the rule into section 3 instead (after the network object NAT rules), then use the <b>after-auto</b> keyword. You can insert a rule anywhere in the applicable section using the <i>line</i> argument.</li> <li>• <b>Source addresses:</b> <ul style="list-style-type: none"> <li>– <b>Real</b>—Specify a network object, group, or the <b>any</b> keyword (see <a href="#">Step 1</a>). Use the <b>any</b> keyword if you want to translate all traffic between the from the real interface to the mapped interface.</li> <li>– <b>Mapped</b>—Specify a network object that contains a host address (see <a href="#">Step 2</a>). You can share this mapped object across different dynamic PAT rules, if desired. To use the mapped interface IP address, specify the <b>interface</b> keyword (routed mode only). For this option, you must configure a specific interface for the <i>mapped_ifc</i>.</li> </ul> </li> <li>• <b>Destination addresses:</b> <ul style="list-style-type: none"> <li>– <b>Mapped</b>—Specify a network object or group, or for static interface NAT with port translation only, specify the <b>interface</b> keyword (see <a href="#">Step 4</a>). If you specify <b>interface</b>, be sure to also configure the <b>service</b> keyword. For this option, you must configure a specific interface for the <i>real_ifc</i>. See the “<a href="#">Static Interface NAT with Port Translation</a>” section on page 27-5 for more information.</li> <li>– <b>Real</b>—Specify a network object or group (see <a href="#">Step 3</a>). For identity NAT, simply use the same object or group for both the real and mapped addresses.</li> </ul> </li> <li>• <b>Destination port</b>—Specify the <b>service</b> keyword along with the real and mapped service objects (see <a href="#">Step 5</a>). For identity port translation, simply use the same service object for both the real and mapped ports.</li> <li>• <b>(For a source-only rule) DNS</b>—The <b>dns</b> keyword translates DNS replies. Be sure DNS inspection is enabled (it is enabled by default). You cannot configure the <b>dns</b> keyword if you configure a <b>destination</b> address. See the “<a href="#">DNS and NAT</a>” section on page 27-21 for more information.</li> <li>• <b>Inactive</b>—To make this rule inactive without having to remove the command, use the <b>inactive</b> keyword. To reactivate it, reenter the whole command without the <b>inactive</b> keyword.</li> <li>• <b>Description</b>—Provide a description up to 200 characters using the <b>description</b> keyword.</li> </ul> |

## Configuring Static NAT or Static NAT with Port Translation

This section describes how to configure a static NAT rule using twice NAT. For more information about static NAT, see the [“Static NAT” section on page 27-3](#).

### Detailed Steps

|        | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p>Network object:</p> <pre>object network obj_name   {host ip_address   subnet   subnet_address netmask   range   ip_address_1 ip_address_2}</pre> <p>Network object group:</p> <pre>object-group network grp_name   {network-object {object net_obj_name     subnet_address netmask     host ip_address}     group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network MyInsNet hostname(config-network-object)# subnet 10.1.1.0 255.255.255.0</pre>           | <p>Configure the real source addresses.</p> <p>You can configure either a network object or a network object group. For more information, see the <a href="#">“Configuring Objects” section on page 11-3</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 2 | <p>Network object:</p> <pre>object network obj_name   {host ip_address   subnet   subnet_address netmask   range   ip_address_1 ip_address_2}</pre> <p>Network object group:</p> <pre>object-group network grp_name   {network-object {object net_obj_name     subnet_address netmask     host ip_address}     group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network MyInsNet_mapped hostname(config-network-object)# subnet 192.168.1.0 255.255.255.0</pre> | <p>Configure the mapped source addresses.</p> <p>You can configure either a network object or a network object group.</p> <p>For static NAT, the mapping is typically one-to-one, so the real addresses have the same quantity as the mapped addresses. You can, however, have different quantities if desired. For more information, see the <a href="#">“Static NAT” section on page 27-3</a>.</p> <p>For static interface NAT with port translation, you can specify the <b>interface</b> keyword instead of a network object/group for the mapped address; you can skip this step. For more information, see the <a href="#">“Static Interface NAT with Port Translation” section on page 27-5</a>.</p> <p>See the <a href="#">“Guidelines and Limitations” section on page 29-2</a> for information about disallowed mapped IP addresses.</p> |

|               | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <p>(Optional)</p> <p>Network object:</p> <pre>object network obj_name   {host ip_address   subnet     subnet_address netmask   range     ip_address_1 ip_address_2}</pre> <p>Network object group:</p> <pre>object-group network grp_name   {network-object {object net_obj_name       subnet_address netmask       host ip_address}     group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network Server1 hostname(config-network-object)# host 209.165.201.8</pre>    | <p>Configure the real destination addresses.</p> <p>You can configure either a network object or a network object group. For more information, see the <a href="#">“Configuring Objects” section on page 11-3</a>.</p> <p>Although the main feature of twice NAT is the inclusion of the destination IP address, the destination address is optional. If you do specify the destination address, you can configure static translation for that address or just use identity NAT for it. You might want to configure twice NAT without a destination address to take advantage of some of the other qualities of twice NAT, including the use of network object groups for real addresses, or manually ordering of rules. For more information, see the <a href="#">“Main Differences Between Network Object NAT and Twice NAT” section on page 27-15</a>.</p>                                                                                                                                                                                                                |
| <b>Step 4</b> | <p>(Optional)</p> <p>Network object:</p> <pre>object network obj_name   {host ip_address   subnet     subnet_address netmask   range     ip_address_1 ip_address_2}</pre> <p>Network object group:</p> <pre>object-group network grp_name   {network-object {object net_obj_name       subnet_address netmask       host ip_address}     group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network Server1_mapped hostname(config-network-object)# host 10.1.1.67</pre> | <p>Configure the mapped destination addresses.</p> <p>You can configure either a network object or a network object group.</p> <p>The destination translation is always static. For identity NAT, simply use the same object or group for both the real and mapped addresses, and skip this step.</p> <p>If you want to translate the destination address, then the static mapping is typically one-to-one, so the real addresses have the same quantity as the mapped addresses. You can, however, have different quantities if desired. For more information, see the <a href="#">“Static NAT” section on page 27-3</a>.</p> <p>For static interface NAT with port translation, you can specify the <b>interface</b> keyword instead of a network object/group for the mapped address; you can skip this step. For more information, see the <a href="#">“Static Interface NAT with Port Translation” section on page 27-5</a>.</p> <p>See the <a href="#">“Guidelines and Limitations” section on page 29-2</a> for information about disallowed mapped IP addresses.</p> |

| Command                                                                                                                                                                                                                                                                                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>Step 5</b> (Optional)</p> <pre>object service obj_name   service {tcp   udp} [source operator     port] [destination operator port]</pre> <p><b>Example:</b></p> <pre>hostname(config)# object service REAL_SRC_SVC hostname(config-service-object)# service tcp source eq 80</pre> <pre>hostname(config)# object service MAPPED_SRC_SVC hostname(config-service-object)# service tcp source eq 8080</pre> | <p>Configure service objects for:</p> <ul style="list-style-type: none"> <li>• Source <i>or</i> destination real TCP or UDP port</li> <li>• Source <i>or</i> destination mapped TCP or UDP port</li> </ul> <p>A service object can contain both a source and destination port. You should specify <i>either</i> the source or the destination port for both service objects. You should only specify both the source and destination ports if your application uses a fixed source port (such as some DNS servers); but fixed source ports are rare. NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports. The “not equal” (<b>neq</b>) operator is not supported.</p> <p>For example, if you want to translate the port for the source host, then configure the source service.</p> |

|        | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 6 | <p><b>nat</b> [(<i>real_ifc</i>,<i>mapped_ifc</i>)] [<i>line</i>   {<b>after-object</b> [<i>line</i>]}]</p> <p><b>source static</b></p> <p><i>real_obj</i> [<i>mapped_obj</i>   <b>interface</b>]</p> <p>[<b>destination static</b> {<i>mapped_obj</i>   <b>interface</b>} <i>real_obj</i>]</p> <p>[<b>service</b> <i>real_src_mapped_dest_svc_obj</i> <i>mapped_src_real_dest_svc_obj</i>] [<b>dns</b>]</p> <p>[<b>unidirectional</b>] [<b>inactive</b>] [<b>description</b> <i>desc</i>]</p> <p><b>Example:</b></p> <pre>hostname(config)# nat (inside,dmz) source static MyInsNet MyInsNet_mapped destination static Server1 Server1 service REAL_SRC_SVC MAPPED_SRC_SVC</pre> | <p>Configures static NAT. See the following guidelines:</p> <ul style="list-style-type: none"> <li>• <b>Interfaces</b>—If you do not specify the real and mapped interfaces, all interfaces are used. You can also specify the keyword <b>any</b> for one or both of the interfaces.</li> <li>• <b>Line</b>—By default, the NAT rule is added to the end of section 1 of the NAT table. See the “<a href="#">NAT Rule Order</a>” section on page 27-19 for more information about sections. If you want to add the rule into section 3 instead (after the network object NAT rules), then use the <b>after-auto</b> keyword. You can insert a rule anywhere in the applicable section using the <i>line</i> argument.</li> <li>• <b>Source addresses:</b> <ul style="list-style-type: none"> <li>– <b>Real</b>—Specify a network object or group (see <a href="#">Step 1</a>).</li> <li>– <b>Mapped</b>—Specify a different network object or group (see <a href="#">Step 2</a>). For static interface NAT with port translation only, you can specify the <b>interface</b> keyword (routed mode only). If you specify <b>interface</b>, be sure to also configure the <b>service</b> keyword (in this case, the service objects should include only the source port). For this option, you must configure a specific interface for the <i>mapped_ifc</i>. See the “<a href="#">Static Interface NAT with Port Translation</a>” section on page 27-5 for more information.</li> </ul> </li> <li>• <b>Destination addresses:</b> <ul style="list-style-type: none"> <li>– <b>Mapped</b>—Specify a network object or group, or for static interface NAT with port translation only, specify the <b>interface</b> keyword (see <a href="#">Step 4</a>). | Command | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|         | <p>(Continued)</p> <ul style="list-style-type: none"> <li>Port—Specify the <b>service</b> keyword along with the real and mapped service objects (see <a href="#">Step 5</a>). For source port translation, the objects must specify the source service. The order of the service objects in the command is <b>service real mapped</b>. For destination port translation, the objects must specify the destination service. The order of the service objects is <b>service mapped real</b>. In the rare case where you specify both the source and destination ports in the object, the first service object contains the real source port/mapped destination port; the second service object contains the mapped source port/real destination port. For identity port translation, simply use the same service object for both the real and mapped ports (source and/or destination ports, depending on your configuration).</li> <li>(For a source-only rule) DNS—The <b>dns</b> keyword translates DNS replies. Be sure DNS inspection is enabled (it is enabled by default). You cannot configure the <b>dns</b> keyword if you configure a <b>destination</b> address. See the “<a href="#">DNS and NAT</a>” section on page 27-21 for more information.</li> <li>Inactive—To make this rule inactive without having to remove the command, use the <b>inactive</b> keyword. To reactivate it, reenter the whole command without the <b>inactive</b> keyword.</li> <li>Description—Provide a description up to 200 characters using the <b>description</b> keyword.</li> </ul> |

## Examples

The following example shows the use of static interface NAT with port translation. Hosts on the outside access an FTP server on the inside by connecting to the outside interface IP address with destination port 65000 through 65004. The traffic is untranslated to the internal FTP server at 192.168.10.100:6500 through :65004. Note that you specify the source port range in the service object (and not the destination port) because you want to translate the source address and port as identified in the command; the destination port is “any.” Because static NAT is bidirectional, “source” and “destination” refers primarily to the command keywords; the actual source and destination address and port in a packet depends on which host sent the packet. In this example, connections are originated from outside to inside, so the “source” address and port of the FTP server is actually the destination address and port in the originating packet.

```
hostname(config)# object service FTP_PASV_PORT_RANGE
hostname(config-service-object)# service tcp source range 65000 65004

hostname(config)# object network HOST_FTP_SERVER
hostname(config-network-object)# host 192.168.10.100

hostname(config)# nat (inside,outside) source static HOST_FTP_SERVER interface service
FTP_PASV_PORT_RANGE FTP_PASV_PORT_RANGE
```

## Configuring Identity NAT

This section describes how to configure an identity NAT rule using twice NAT. You configure identity NAT using a static NAT rule where you map an address to itself. For more information about identity NAT, see the [“Identity NAT” section on page 27-11](#).

### Detailed Steps

|        | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p>Network object:</p> <pre>object network obj_name   {host ip_address   subnet   subnet_address netmask   range   ip_address_1 ip_address_2}</pre> <p>Network object group:</p> <pre>object-group network grp_name   {network-object {object net_obj_name     subnet_address netmask     host ip_address}     group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network MyInsNet hostname(config-network-object)# subnet 10.1.1.0 255.255.255.0</pre>       | <p>Configure the real source addresses.</p> <p>You can configure either a network object or a network object group. For more information, see the <a href="#">“Configuring Objects” section on page 11-3</a>.</p> <p>These are the addresses on which you want to perform identity NAT. If you want to perform identity NAT for all addresses, you can instead use the keywords <b>any any</b>; skip this step.</p>                                                                                                                                                                                                                                                                                                                                                 |
| Step 2 | <p>(Optional)</p> <p>Network object:</p> <pre>object network obj_name   {host ip_address   subnet   subnet_address netmask   range   ip_address_1 ip_address_2}</pre> <p>Network object group:</p> <pre>object-group network grp_name   {network-object {object net_obj_name     subnet_address netmask     host ip_address}     group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network Server1 hostname(config-network-object)# host 209.165.201.8</pre> | <p>Configure the real destination addresses.</p> <p>You can configure either a network object or a network object group.</p> <p>Although the main feature of twice NAT is the inclusion of the destination IP address, the destination address is optional. If you do specify the destination address, you can configure static translation for that address or just use identity NAT for it. You might want to configure twice NAT without a destination address to take advantage of some of the other qualities of twice NAT, including the use of network object groups for real addresses, or manually ordering of rules. For more information, see the <a href="#">“Main Differences Between Network Object NAT and Twice NAT” section on page 27-15</a>.</p> |

|        | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | (Optional)                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Configure the mapped destination addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|        | <p>Network object:</p> <pre>object network obj_name   {host ip_address   subnet   subnet_address netmask   range   ip_address_1 ip_address_2}</pre> <p>Network object group:</p> <pre>object-group network grp_name   {network-object {object net_obj_name     subnet_address netmask     host ip_address}     group-object grp_obj_name}</pre> <p><b>Example:</b></p> <pre>hostname(config)# object network Server1_mapped hostname(config-network-object)# host 10.1.1.67</pre> | <p>You can configure either a network object or a network object group.</p> <p>The destination translation is always static. For identity NAT, simply use the same object or group for both the real and mapped addresses, and skip this step.</p> <p>If you want to translate the destination address, then the static mapping is typically one-to-one, so the real addresses have the same quantity as the mapped addresses. You can, however, have different quantities if desired. For more information, see the <a href="#">“Static NAT” section on page 27-3</a>.</p> <p>For static interface NAT with port translation, you can specify the <b>interface</b> keyword instead of a network object/group for the mapped address. For more information, see the <a href="#">“Static Interface NAT with Port Translation” section on page 27-5</a>.</p> <p>See the <a href="#">“Guidelines and Limitations” section on page 29-2</a> for information about disallowed mapped IP addresses.</p> |
| Step 4 | (Optional)                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Configure service objects for:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|        | <pre>object service obj_name   service {tcp   udp} [source operator   port] [destination operator port]</pre> <p><b>Example:</b></p> <pre>hostname(config)# object service REAL_SRC_SVC hostname(config-service-object)# service tcp source eq 80  hostname(config)# object service MAPPED_SRC_SVC hostname(config-service-object)# service tcp source eq 8080</pre>                                                                                                              | <ul style="list-style-type: none"> <li>• Source <i>or</i> destination real TCP or UDP port</li> <li>• Source <i>or</i> destination mapped TCP or UDP port</li> </ul> <p>A service object can contain both a source and destination port. You should specify <i>either</i> the source or the destination port for both service objects. You should only specify both the source and destination ports if your application uses a fixed source port (such as some DNS servers); but fixed source ports are rare. NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports. The “not equal” (<b>neq</b>) operator is not supported.</p> <p>For example, if you want to translate the port for the source host, then configure the source service.</p>                                                      |

|        | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 5 | <pre> <b>nat</b> [(<i>real_ifc</i>,<i>mapped_ifc</i>)] [<i>line</i>   {<b>after-object</b> [<i>line</i>]}] <b>source static</b> {<i>nw_obj nw_obj</i>   <b>any any</b>} [<b>destination static</b> {<i>mapped_obj</i>   <b>interface</b>} <i>real_obj</i>] [<b>service</b> <i>real_src_mapped_dest_svc_obj</i> <i>mapped_src_real_dest_svc_obj</i>] [<b>inactive</b>] [<b>description</b> <i>desc</i>] </pre> <p><b>Example:</b></p> <pre> hostname(config)# nat (inside,outside) source static MyInsNet MyInsNet destination static Server1 Server1 </pre> | <p>Configures identity NAT. See the following guidelines:</p> <ul style="list-style-type: none"> <li>• <b>Interfaces</b>—If you do not specify the real and mapped interfaces, all interfaces are used. You can also specify the keyword <b>any</b> for one or both of the interfaces.</li> <li>• <b>Line</b>—By default, the NAT rule is added to the end of section 1 of the NAT table. See the “<a href="#">NAT Rule Order</a>” section on page 27-19 for more information about sections. If you want to add the rule into section 3 instead (after the network object NAT rules), then use the <b>after-auto</b> keyword. You can insert a rule anywhere in the applicable section using the <i>line</i> argument.</li> <li>• <b>Source addresses</b>—Specify a network object, group, or the <b>any</b> keyword for both the real and mapped addresses (see <a href="#">Step 1</a>).</li> <li>• <b>Destination addresses:</b> <ul style="list-style-type: none"> <li>– <b>Mapped</b>—Specify a network object or group, or for static interface NAT with port translation only, specify the <b>interface</b> keyword (routed mode only) (see <a href="#">Step 3</a>). If you specify <b>interface</b>, be sure to also configure the <b>service</b> keyword (in this case, the service objects should include only the destination port). For this option, you must configure a specific interface for the <i>real_ifc</i>. See the “<a href="#">Static Interface NAT with Port Translation</a>” section on page 27-5 for more information.</li> <li>– <b>Real</b>—Specify a network object or group (see <a href="#">Step 2</a>). For identity NAT, simply use the same object or group for both the real and mapped addresses.</li> </ul> </li> <li>• <b>Port</b>—Specify the <b>service</b> keyword along with the real and mapped service objects (see <a href="#">Step 4</a>). For source port translation, the objects must specify the source service. The order of the service objects in the command is <b>service real mapped</b>. For destination port translation, the objects must specify the destination service. The order of the service objects is <b>service mapped real</b>. In the rare case where you specify both the source and destination ports in the object, the first service object contains the real source port/mapped destination port; the second service object contains the mapped source port/real destination port. For identity port translation, simply use the same service object for both the real and mapped ports (source and/or destination ports, depending on your configuration).</li> <li>• <b>Inactive</b>—To make this rule inactive without having to remove the command, use the <b>inactive</b> keyword. To reactivate it, reenter the whole command without the <b>inactive</b> keyword.</li> <li>• <b>Description</b>—Provide a description up to 200 characters using the <b>description</b> keyword.</li> </ul> |

# Monitoring Twice NAT

To monitor twice NAT, enter one of the following commands:

| Command                    | Purpose                                                                                                         |
|----------------------------|-----------------------------------------------------------------------------------------------------------------|
| <code>show nat</code>      | Shows NAT statistics, including hits for each NAT rule.                                                         |
| <code>show nat pool</code> | Shows NAT pool statistics, including the addresses and ports allocated, and how many times they were allocated. |
| <code>show xlate</code>    | Shows current NAT session information.                                                                          |

## Configuration Examples for Twice NAT

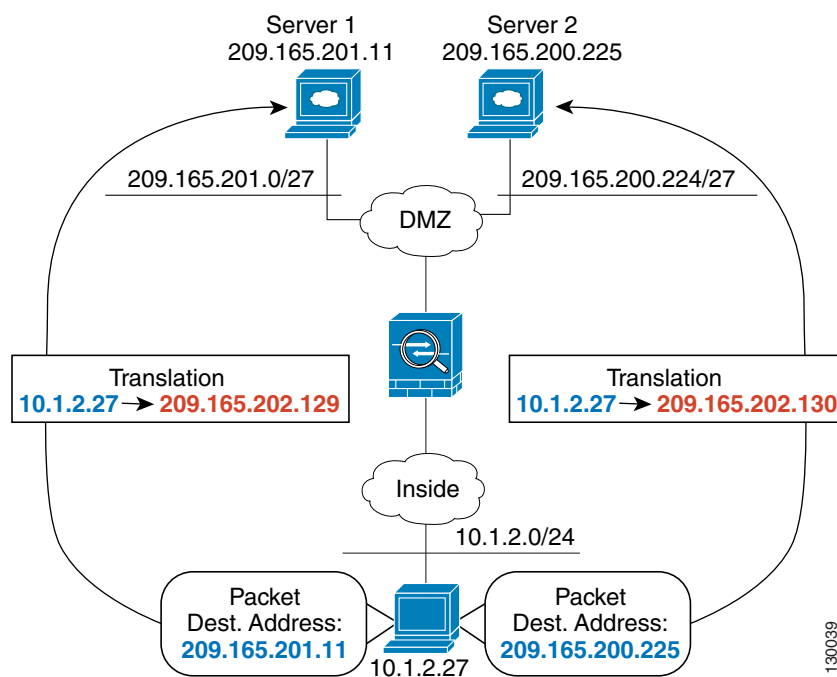

This section includes the following configuration examples:

- [Different Translation Depending on the Destination \(Dynamic PAT\), page 29-20](#)
- [Different Translation Depending on the Destination Address and Port \(Dynamic PAT\), page 29-22](#)

### Different Translation Depending on the Destination (Dynamic PAT)

Figure 29-1 shows a host on the 10.1.2.0/24 network accessing two different servers. When the host accesses the server at 209.165.201.11, the real address is translated to 209.165.202.129:port. When the host accesses the server at 209.165.200.225, the real address is translated to 209.165.202.130:port.

**Figure 29-1** Twice NAT with Different Destination Addresses

---

**Step 1** Add a network object for the inside network:

```
hostname(config)# object network myInsideNetwork
hostname(config-network-object)# subnet 10.1.2.0 255.255.255.0
```

**Step 2** Add a network object for the DMZ network 1:

```
hostname(config)# object network DMZnetwork1
hostname(config-network-object)# subnet 209.165.201.0 255.255.255.224
```

**Step 3** Add a network object for the PAT address:

```
hostname(config)# object network PATaddress1
hostname(config-network-object)# host 209.165.202.129
```

**Step 4** Configure the first twice NAT rule:

```
hostname(config)# nat (inside,dmz) source dynamic myInsideNetwork PATaddress1 destination
static DMZnetwork1 DMZnetwork1
```

Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the real and mapped destination addresses.

By default, the NAT rule is added to the end of section 1 of the NAT table. See the [“Configuring Dynamic PAT \(Hide\)” section on page 29-8](#) for more information about specifying the section and line number for the NAT rule.

**Step 5** Add a network object for the DMZ network 2:

```
hostname(config)# object network DMZnetwork2
hostname(config-network-object)# subnet 209.165.200.224 255.255.255.224
```

**Step 6** Add a network object for the PAT address:

```
hostname(config)# object network PATaddress2
hostname(config-network-object)# host 209.165.202.130
```

**Step 7** Configure the second twice NAT rule:

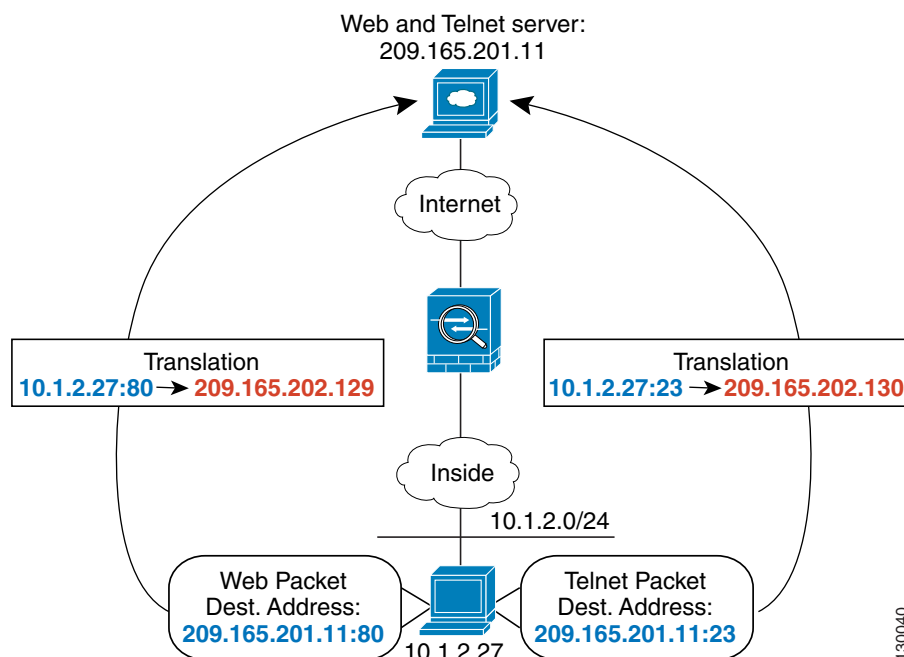

```
hostname(config)# nat (inside,dmz) source dynamic myInsideNetwork PATaddress2 destination
static DMZnetwork2 DMZnetwork2
```

---

## Different Translation Depending on the Destination Address and Port (Dynamic PAT)

Figure 29-2 shows the use of source and destination ports. The host on the 10.1.2.0/24 network accesses a single host for both web services and Telnet services. When the host accesses the server for web services, the real address is translated to 209.165.202.129:port. When the host accesses the same server for Telnet services, the real address is translated to 209.165.202.130:port.

**Figure 29-2** Twice NAT with Different Destination Ports

**Step 1** Add a network object for the inside network:

```
hostname(config)# object network myInsideNetwork
hostname(config-network-object)# subnet 10.1.2.0 255.255.255.0
```

**Step 2** Add a network object for the Telnet/Web server:

```
hostname(config)# object network TelnetWebServer
hostname(config-network-object)# host 209.165.201.11
```

**Step 3** Add a network object for the PAT address when using Telnet:

```
hostname(config)# object network PATaddress1
hostname(config-network-object)# host 209.165.202.129
```

**Step 4** Add a service object for Telnet:

```
hostname(config)# object service TelnetObj
hostname(config-network-object)# service tcp destination eq telnet
```

**Step 5** Configure the first twice NAT rule:

```
hostname(config)# nat (inside,outside) source dynamic myInsideNetwork PATaddress1
destination static TelnetWebServer TelnetWebServer service TelnetObj TelnetObj
```

Because you do not want to translate the destination address or port, you need to configure identity NAT for them by specifying the same address for the real and mapped destination addresses, and the same port for the real and mapped service.

By default, the NAT rule is added to the end of section 1 of the NAT table. See the [“Configuring Dynamic PAT \(Hide\)” section on page 29-8](#) for more information about specifying the section and line number for the NAT rule.

**Step 6** Add a network object for the PAT address when using HTTP:

```
hostname(config)# object network PATaddress2
hostname(config-network-object)# host 209.165.202.130
```

**Step 7** Add a service object for HTTP:

```
hostname(config)# object service HTTPObj
hostname(config-network-object)# service tcp destination eq http
```

**Step 8** Configure the second twice NAT rule:

```
hostname(config)# nat (inside,outside) source dynamic myInsideNetwork PATaddress2
destination static TelnetWebServer TelnetWebServer service HTTPObj HTTPObj
```

## Feature History for Twice NAT

[Table 29-1](#) lists each feature change and the platform release in which it was implemented.

**Table 29-1** Feature History for Twice NAT

| Feature Name | Platform Releases | Feature Information                                                                                                                                                                                                        |
|--------------|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Twice NAT    | 8.3(1)            | Twice NAT lets you identify both the source and destination address in a single rule.<br><br>The following commands were modified or introduced: <b>nat</b> , <b>show nat</b> , <b>show xlate</b> , <b>show nat pool</b> . |

## **PART 6**

### **Configuring Service Policies Using the Modular Policy Framework**

## CHAPTER 30

# Configuring a Service Policy Using the Modular Policy Framework

---

Service policies using Modular Policy Framework provide a consistent and flexible way to configure adaptive security appliance features. For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications. A service policy consists of multiple actions applied to an interface or applied globally.

This chapter includes the following sections:

- [Information About Service Policies, page 30-1](#)
- [Licensing Requirements for Service Policies, page 30-6](#)
- [Guidelines and Limitations, page 30-6](#)
- [Default Settings, page 30-8](#)
- [Task Flows for Configuring Service Policies, page 30-9](#)
- [Identifying Traffic \(Layer 3/4 Class Maps\), page 30-12](#)
- [Defining Actions \(Layer 3/4 Policy Map\), page 30-15](#)
- [Applying Actions to an Interface \(Service Policy\), page 30-17](#)
- [Monitoring Modular Policy Framework, page 30-18](#)
- [Configuration Examples for Modular Policy Framework, page 30-18](#)
- [Feature History for Service Policies, page 30-21](#)

## Information About Service Policies

This section describes how service policies work and includes the following topics:

- [Supported Features for Through Traffic, page 30-2](#)
- [Supported Features for Management Traffic, page 30-2](#)
- [Feature Directionality, page 30-2](#)
- [Feature Matching Within a Service Policy, page 30-3](#)
- [Order in Which Multiple Feature Actions are Applied, page 30-4](#)
- [Incompatibility of Certain Feature Actions, page 30-5](#)
- [Feature Matching for Multiple Service Policies, page 30-6](#)

## Supported Features for Through Traffic

Table 30-1 lists the features supported by Modular Policy Framework.

**Table 30-1**      *Modular Policy Framework*

| Feature                                                                           | See:                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application inspection (multiple types)                                           | <ul style="list-style-type: none"> <li>Chapter 38, “Getting Started With Application Layer Protocol Inspection.”</li> <li>Chapter 39, “Configuring Inspection of Basic Internet Protocols.”</li> <li>Chapter 41, “Configuring Inspection of Database and Directory Protocols.”</li> <li>Chapter 42, “Configuring Inspection for Management Application Protocols.”</li> <li>Chapter 40, “Configuring Inspection for Voice and Video Protocols.”</li> </ul> |
| CSC                                                                               | Chapter 56, “Configuring the Content Security and Control Application on the CSC SSM.”                                                                                                                                                                                                                                                                                                                                                                     |
| IPS                                                                               | Chapter 55, “Configuring the IPS Module.”                                                                                                                                                                                                                                                                                                                                                                                                                  |

| QoS traffic shaping, hierarchical priority queue                                  | Chapter 50, “Configuring QoS.”                                                                                                                                                                                                                                                                                                                                                                                                                             |
| TCP and UDP connection limits and timeouts, and TCP sequence number randomization | Chapter 49, “Configuring Connection Settings.”                                                                                                                                                                                                                                                                                                                                                                                                             |
| TCP normalization                                                                 | Chapter 49, “Configuring Connection Settings.”                                                                                                                                                                                                                                                                                                                                                                                                             |
| TCP state bypass                                                                  | Chapter 49, “Configuring Connection Settings.”                                                                                                                                                                                                                                                                                                                                                                                                             |

## Supported Features for Management Traffic

Modular Policy Framework supports the following features for management traffic:

- Application inspection for RADIUS accounting traffic—See Chapter 42, “Configuring Inspection for Management Application Protocols.”
- Connection limits—See Chapter 49, “Configuring Connection Settings.”

## Feature Directionality

Actions are applied to traffic bidirectionally or unidirectionally depending on the feature. For features that are applied bidirectionally, all traffic that enters or exits the interface to which you apply the policy map is affected if the traffic matches the class map for both directions.

**Note**

When you use a global policy, all features are unidirectional; features that are normally bidirectional when applied to a single interface only apply to the ingress of each interface when applied globally. Because the policy is applied to all interfaces, the policy will be applied in both directions so bidirectionality in this case is redundant.

For features that are applied unidirectionally, for example QoS priority queue, only traffic that enters (or exits, depending on the feature) the interface to which you apply the policy map is affected. See [Table 30-2](#) for the directionality of each feature.

**Table 30-2**      **Feature Directionality**

| Feature                                                                           | Single Interface Direction | Global Direction |
|-----------------------------------------------------------------------------------|----------------------------|------------------|
| Application inspection (multiple types)                                           | Bidirectional              | Ingress          |
| CSC                                                                               | Bidirectional              | Ingress          |
| IPS                                                                               | Bidirectional              | Ingress          |
| NetFlow Secure Event Logging filtering                                            | N/A                        | Ingress          |
| QoS input policing                                                                | Ingress                    | Ingress          |
| QoS output policing                                                               | Egress                     | Egress           |
| QoS standard priority queue                                                       | Egress                     | Egress           |
| QoS traffic shaping, hierarchical priority queue                                  | Egress                     | Egress           |
| TCP and UDP connection limits and timeouts, and TCP sequence number randomization | Bidirectional              | Ingress          |
| TCP normalization                                                                 | Bidirectional              | Ingress          |
| TCP state bypass                                                                  | Bidirectional              | Ingress          |

## Feature Matching Within a Service Policy

See the following information for how a packet matches class maps in a policy map for a given interface:

1. A packet can match only one class map in the policy map for each feature type.
2. When the packet matches a class map for a feature type, the adaptive security appliance does not attempt to match it to any subsequent class maps for that feature type.
3. If the packet matches a subsequent class map for a different feature type, however, then the adaptive security appliance also applies the actions for the subsequent class map, if supported. See the [“Incompatibility of Certain Feature Actions”](#) section on [page 30-5](#) for more information about unsupported combinations.

For example, if a packet matches a class map for connection limits, and also matches a class map for application inspection, then both actions are applied.

If a packet matches a class map for HTTP inspection, but also matches another class map that includes HTTP inspection, then the second class map actions are not applied.

**Note**

Application inspection includes multiple inspection types, and each inspection type is a separate feature when you consider the matching guidelines above.

## Order in Which Multiple Feature Actions are Applied

The order in which different types of actions in a policy map are performed is independent of the order in which the actions appear in the policy map.

**Note**

---

NetFlow Secure Event Logging filtering is order-independent.

---

Actions are performed in the following order:

1. QoS input policing
2. TCP normalization, TCP and UDP connection limits and timeouts, TCP sequence number randomization, and TCP state bypass.

**Note**

---

When a the adaptive security appliance performs a proxy service (such as AAA or CSC) or it modifies the TCP payload (such as FTP inspection), the TCP normalizer acts in dual mode, where it is applied before and after the proxy or payload modifying service.

---

3. CSC
4. Application inspection (multiple types)

The order of application inspections applied when a class of traffic is classified for multiple inspections is as follows. Only one inspection type can be applied to the same traffic. WAAS inspection is an exception, because it can be applied along with other inspections for the same traffic. See the [“Incompatibility of Certain Feature Actions” section on page 30-5](#) for more information.

- j. MGCP
- k. NetBIOS
- l. PPTP
- m. Sun RPC
- n. RSH
- o. RTSP
- p. SIP
- q. Skinny
- r. SMTP

- s. SNMP
- t. SQL\*Net
- u. TFTP
- v. XDMCP
- w. DCERPC
- x. Instant Messaging

**Note**

RADIUS accounting is not listed because it is the only inspection allowed on management traffic. WAAS is not listed because it can be configured along with other inspections for the same traffic.

- 5. IPS
- 6. QoS output policing
- 7. QoS standard priority queue
- 8. QoS traffic shaping, hierarchical priority queue

## Incompatibility of Certain Feature Actions

Some features are not compatible with each other for the same traffic. For example, you cannot configure QoS priority queueing and QoS policing for the same set of traffic. Also, most inspections should not be combined with another inspection, so the adaptive security appliance only applies one inspection if you configure multiple inspections for the same traffic. In this case, the feature that is applied is the higher priority feature in the list in the [“Order in Which Multiple Feature Actions are Applied”](#) section on page 30-4.

For information about compatibility of each feature, see the chapter or section for your feature.

**Note**

The **match default-inspection-traffic** command, which is used in the default global policy, is a special CLI shortcut to match the default ports for all inspections. When used in a policy map, this class map ensures that the correct inspection is applied to each packet, based on the destination port of the traffic. For example, when UDP traffic for port 69 reaches the adaptive security appliance, then the adaptive security appliance applies the TFTP inspection; when TCP traffic for port 21 arrives, then the adaptive security appliance applies the FTP inspection. So in this case only, you can configure multiple inspections for the same class map. Normally, the adaptive security appliance does not use the port number to determine which inspection to apply, thus giving you the flexibility to apply inspections to non-standard ports, for example.

An example of a misconfiguration is if you configure multiple inspections in the same policy map and do not use the default-inspection-traffic shortcut. In [Example 30-1](#), traffic destined to port 21 is mistakenly configured for both FTP and HTTP inspection. In [Example 30-2](#), traffic destined to port 80 is mistakenly configured for both FTP and HTTP inspection. In both cases of misconfiguration examples, only the FTP inspection is applied, because FTP comes before HTTP in the order of inspections applied.

### **Example 30-1 Misconfiguration for FTP packets: HTTP Inspection Also Configured**

```
class-map ftp
```

```

match port tcp eq 21
class-map http
  match port tcp eq 21 [it should be 80]
policy-map test
  class ftp
    inspect ftp
  class http
    inspect http

```

**Example 30-2 Misconfiguration for HTTP packets: FTP Inspection Also Configured**

```

class-map ftp
  match port tcp eq 80 [it should be 21]
class-map http
  match port tcp eq 80
policy-map test
  class http
    inspect http
  class ftp
    inspect ftp

```

## Feature Matching for Multiple Service Policies

For TCP and UDP traffic (and ICMP when you enable stateful ICMP inspection), service policies operate on traffic flows, and not just individual packets. If traffic is part of an existing connection that matches a feature in a policy on one interface, that traffic flow cannot also match the same feature in a policy on another interface; only the first policy is used.

For example, if HTTP traffic matches a policy on the inside interface to inspect HTTP traffic, and you have a separate policy on the outside interface for HTTP inspection, then that traffic is not also inspected on the egress of the outside interface. Similarly, the return traffic for that connection will not be inspected by the ingress policy of the outside interface, nor by the egress policy of the inside interface.

For traffic that is not treated as a flow, for example ICMP when you do not enable stateful ICMP inspection, returning traffic can match a different policy map on the returning interface. For example, if you configure IPS on the inside and outside interfaces, but the inside policy uses virtual sensor 1 while the outside policy uses virtual sensor 2, then a non-stateful Ping will match virtual sensor 1 outbound, but will match virtual sensor 2 inbound.

## Licensing Requirements for Service Policies

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

**Context Mode Guidelines**

Supported in single and multiple context mode.

**Firewall Mode Guidelines**

Supported in routed and transparent firewall mode.

**IPv6 Guidelines**

Supports IPv6 for the following features:

- Application inspection for FTP, HTTP, ICMP, SIP, SMTP and IPSec-pass-thru
- IPS
- NetFlow Secure Event Logging filtering
- TCP and UDP connection limits and timeouts, TCP sequence number randomization
- TCP normalization
- TCP state bypass

**Class Map Guidelines**

The maximum number of class maps of all types is 255 in single mode or per context in multiple mode. Class maps include the following types:

- Layer 3/4 class maps (for through traffic and management traffic)
- Inspection class maps
- Regular expression class maps
- **match** commands used directly underneath an inspection policy map

This limit also includes default class maps of all types, limiting user-configured class maps to approximately 235. See the [“Default Class Maps” section on page 30-9](#).

**Policy Map Guidelines**

See the following guidelines for using policy maps:

- You can only assign one policy map per interface. (However you can create up to 64 policy maps in the configuration.)
- You can apply the same policy map to multiple interfaces.
- You can identify up to 63 Layer 3/4 class maps in a Layer 3/4 policy map.
- For each class map, you can assign multiple actions from one or more feature types, if supported. See the [“Incompatibility of Certain Feature Actions” section on page 30-5](#).

**Service Policy Guidelines**

- Interface service policies take precedence over the global service policy for a given feature. For example, if you have a global policy with FTP inspection, and an interface policy with TCP normalization, then both FTP inspection and TCP normalization are applied to the interface. However, if you have a global policy with FTP inspection, and an interface policy with FTP inspection, then only the interface policy FTP inspection is applied to that interface.
- You can only apply one global policy. For example, you cannot create a global policy that includes feature set 1, and a separate global policy that includes feature set 2. All features must be included in a single policy.

# Default Settings

The following topics describe the default settings for Modular Policy Framework:

- [Default Configuration, page 30-8](#)
- [Default Class Maps, page 30-9](#)

## Default Configuration

By default, the configuration includes a policy that matches all default application inspection traffic and applies certain inspections to the traffic on all interfaces (a global policy). Not all inspections are enabled by default. You can only apply one global policy, so if you want to alter the global policy, you need to either edit the default policy or disable it and apply a new one. (An interface policy overrides the global policy for a particular feature.)

The default policy includes the following application inspections:

- DNS inspection for the maximum message length of 512 bytes
- FTP
- H323 (H225)
- H323 (RAS)
- RSH
- RTSP
- ESMTP
- SQLnet
- Skinny (SCCP)
- SunRPC
- XDMCP
- SIP
- NetBios
- TFTP

The default policy configuration includes the following commands:

```
class-map inspection_default
  match default-inspection-traffic
policy-map type inspect dns preset_dns_map
  parameters
    message-length maximum 512
policy-map global_policy
  class inspection_default
    inspect dns preset_dns_map
    inspect ftp
    inspect h323 h225
    inspect h323 ras
    inspect rsh
    inspect rtsp
    inspect esmtp
    inspect sqlnet
    inspect skinny
    inspect sunrpc
```

```
inspect xdmcp
inspect sip
inspect netbios
inspect tftp
service-policy global_policy global
```

**Note**

See the [“Incompatibility of Certain Feature Actions”](#) section on page 30-5 for more information about the special **match default-inspection-traffic** command used in the default class map.

## Default Class Maps

The configuration includes a default Layer 3/4 class map that the adaptive security appliance uses in the default global policy called default-inspection-traffic; it matches the default inspection traffic. This class, which is used in the default global policy, is a special shortcut to match the default ports for all inspections. When used in a policy, this class ensures that the correct inspection is applied to each packet, based on the destination port of the traffic. For example, when UDP traffic for port 69 reaches the adaptive security appliance, then the adaptive security appliance applies the TFTP inspection; when TCP traffic for port 21 arrives, then the adaptive security appliance applies the FTP inspection. So in this case only, you can configure multiple inspections for the same class map. Normally, the adaptive security appliance does not use the port number to determine which inspection to apply, thus giving you the flexibility to apply inspections to non-standard ports, for example.

```
class-map inspection_default
match default-inspection-traffic
```

Another class map that exists in the default configuration is called class-default, and it matches all traffic. This class map appears at the end of all Layer 3/4 policy maps and essentially tells the adaptive security appliance to not perform any actions on all other traffic. You can use the class-default class if desired, rather than making your own **match any** class map. In fact, some features are only available for class-default, such as QoS traffic shaping.

```
class-map class-default
match any
```

## Task Flows for Configuring Service Policies

This section includes the following topics:

- [Task Flow for Using the Modular Policy Framework, page 30-9](#)
- [Task Flow for Configuring Hierarchical Policy Maps for QoS Traffic Shaping, page 30-11](#)

### Task Flow for Using the Modular Policy Framework

To configure Modular Policy Framework, perform the following steps:

- 
- Step 1** Identify the traffic—Identify the traffic on which you want to perform Modular Policy Framework actions by creating Layer 3/4 class maps.

For example, you might want to perform actions on all traffic that passes through the adaptive security appliance; or you might only want to perform certain actions on traffic from 10.1.1.0/24 to any destination address.

See the “Identifying Traffic (Layer 3/4 Class Maps)” section on page 30-12.

- Step 2** Perform additional actions on some inspection traffic—If one of the actions you want to perform is application inspection, and you want to perform additional actions on some inspection traffic, then create an inspection policy map. The inspection policy map identifies the traffic and specifies what to do with it. For example, you might want to drop all HTTP requests with a body length greater than 1000 bytes.

You can create a self-contained inspection policy map that identifies the traffic directly with **match** commands, or you can create an inspection class map for reuse or for more complicated matching. See the “Defining Actions in an Inspection Policy Map” section on page 31-2 and the “Identifying Traffic in an Inspection Class Map” section on page 31-5.

- Step 3** Create a regular expression—If you want to match text with a regular expression within inspected packets, you can create a regular expression or a group of regular expressions (a regular expression class map). Then, when you define the traffic to match for the inspection policy map, you can call on an existing regular expression.

For example, you might want to drop all HTTP requests with a URL including the text “example.com.”

See the “Creating a Regular Expression” section on page 11-12 and the “Creating a Regular Expression Class Map” section on page 11-15.

- Step 4** Define the actions you want to perform and determine on which interfaces you want to apply the policy map—Define the actions you want to perform on each Layer 3/4 class map by creating a Layer 3/4 policy map. Then, determine on which interfaces you want to apply the policy map using a service policy.

See the “[Defining Actions \(Layer 3/4 Policy Map\)](#)” section on page 30-15 and the “[Applying Actions to an Interface \(Service Policy\)](#)” section on page 30-17.

## Task Flow for Configuring Hierarchical Policy Maps for QoS Traffic Shaping

If you enable QoS traffic shaping for a class map, then you can optionally enable priority queueing for a subset of shaped traffic. To do so, you need to create a policy map for the priority queueing, and then within the traffic shaping policy map, you can call the priority class map. Only the traffic shaping class map is applied to an interface.

See [Chapter 50, “Information About QoS,”](#) for more information about this feature.

Hierarchical policy maps are only supported for traffic shaping and priority queueing.

To implement a hierarchical policy map, perform the following steps:

- Step 1** Identify the prioritized traffic according to the “[Identifying Traffic \(Layer 3/4 Class Maps\)](#)” section on page 30-12.  
You can create multiple class maps to be used in the hierarchical policy map.
- Step 2** Create a policy map according to the “[Defining Actions \(Layer 3/4 Policy Map\)](#)” section on page 30-15, and identify the sole action for each class map as **priority**.
- Step 3** Create a separate policy map according to the “[Defining Actions \(Layer 3/4 Policy Map\)](#)” section on page 30-15, and identify the **shape** action for the **class-default** class map.

Traffic shaping can only be applied to the **class-default** class map.

- Step 4** For the same class map, identify the priority policy map that you created in Step 2 using the **service-policy** *priority\_policy\_map* command.
- Step 5** Apply the shaping policy map to the interface according to [“Applying Actions to an Interface \(Service Policy\)” section on page 30-17](#).

## Identifying Traffic (Layer 3/4 Class Maps)

A Layer 3/4 class map identifies Layer 3 and 4 traffic to which you want to apply actions. You can create multiple Layer 3/4 class maps for each Layer 3/4 policy map.

This section includes the following topics:

- [Creating a Layer 3/4 Class Map for Through Traffic, page 30-12](#)
- [Creating a Layer 3/4 Class Map for Management Traffic, page 30-15](#)

## Creating a Layer 3/4 Class Map for Through Traffic

A Layer 3/4 class map matches traffic based on protocols, ports, IP addresses and other Layer 3 or 4 attributes.

### Detailed Steps

- Step 1** Create a Layer 3/4 class map by entering the following command:

```
hostname(config)# class-map class_map_name
hostname(config-cmap)#
```

Where *class\_map\_name* is a string up to 40 characters in length. The name “class-default” is reserved. All types of class maps use the same name space, so you cannot reuse a name already used by another type of class map. The CLI enters class-map configuration mode.

- Step 2** (Optional) Add a description to the class map by entering the following command:

```
hostname(config-cmap)# description string
```

- Step 3** Define the traffic to include in the class by matching one of the following characteristics. Unless otherwise specified, you can include only one **match** command in the class map.

- Any traffic—The class map matches all traffic.

```
hostname(config-cmap)# match any
```

#### Note

For features that support IPv6 (see the [“Guidelines and Limitations” section on page 30-6](#)), then the **match any** and **match default-inspection-traffic** commands are the only commands that match IPv6 traffic. For example, you cannot match an IPv6 access list.

- Access list—The class map matches traffic specified by an extended access list. If the adaptive security appliance is operating in transparent firewall mode, you can use an EtherType access list.

```
hostname(config-cmap)# match access-list access_list_name
```

For more information about creating access lists, see [Chapter 13, “Adding an Extended Access List,”](#) or [Chapter 14, “Adding an EtherType Access List.”](#)

For information about creating access lists with NAT, see the [“IP Addresses Used for Access Lists When You Use NAT”](#) section on page 12-3.

- TCP or UDP destination ports—The class map matches a single port or a contiguous range of ports.

```
hostname(config-cmap)# match port {tcp | udp} {eq port_num | range port_num port_num}
```

**Tip**

For applications that use multiple, non-contiguous ports, use the **match access-list** command and define an ACE to match each port.

For a list of ports you can specify, see the [“TCP and UDP Ports”](#) section on page B-11.

For example, enter the following command to match TCP packets on port 80 (HTTP):

```
hostname(config-cmap)# match tcp eq 80
```

- Default traffic for inspection—The class map matches the default TCP and UDP ports used by all applications that the adaptive security appliance can inspect.

```
hostname(config-cmap)# match default-inspection-traffic
```

This command, which is used in the default global policy, is a special CLI shortcut that when used in a policy map, ensures that the correct inspection is applied to each packet, based on the destination port of the traffic. For example, when UDP traffic for port 69 reaches the adaptive security appliance, then the adaptive security appliance applies the TFTP inspection; when TCP traffic for port 21 arrives, then the adaptive security appliance applies the FTP inspection. So in this case only, you can configure multiple inspections for the same class map (with the exception of WAAS inspection, which can be configured with other inspections. See the [“Incompatibility of Certain Feature Actions”](#) section on page 30-5 for more information about combining actions). Normally, the adaptive security appliance does not use the port number to determine the inspection applied, thus giving you the flexibility to apply inspections to non-standard ports, for example.

See the [“Default Settings”](#) section on page 38-4 for a list of default ports. Not all applications whose ports are included in the **match default-inspection-traffic** command are enabled by default in the policy map.

You can specify a **match access-list** command along with the **match default-inspection-traffic** command to narrow the matched traffic. Because the **match default-inspection-traffic** command specifies the ports and protocols to match, any ports and protocols in the access list are ignored.

**Tip**

We suggest that you only inspect traffic on ports on which you expect application traffic; if you inspect all traffic, for example using **match any**, the adaptive security appliance performance can be impacted.

**Note**

For features that support IPv6 (see the [“Guidelines and Limitations”](#) section on page 30-6), then the **match any** and **match default-inspection-traffic** commands are the only commands that match IPv6 traffic. For example, you cannot match an IPv6 access list.

- DSCP value in an IP header—The class map matches up to eight DSCP values.

```
hostname(config-cmap)# match dscp value1 [value2] [...] [value8]
```

For example, enter the following:

```
hostname(config-cmap)# match dscp af43 cs1 ef
```

- **Precedence**—The class map matches up to four precedence values, represented by the TOS byte in the IP header.

```
hostname(config-cmap)# match precedence value1 [value2] [value3] [value4]
```

where *value1* through *value4* can be 0 to 7, corresponding to the possible precedences.

- **RTP traffic**—The class map matches RTP traffic.

```
hostname(config-cmap)# match rtp starting_port range
```

The *starting\_port* specifies an even-numbered UDP destination port between 2000 and 65534. The *range* specifies the number of additional UDP ports to match above the *starting\_port*, between 0 and 16383.

- **Tunnel group traffic**—The class map matches traffic for a tunnel group to which you want to apply QoS.

```
hostname(config-cmap)# match tunnel-group name
```

You can also specify one other **match** command to refine the traffic match. You can specify any of the preceding commands, except for the **match any**, **match access-list**, or **match default-inspection-traffic** commands. Or you can enter the following command to police each flow:

```
hostname(config-cmap)# match flow ip destination address
```

All traffic going to a unique IP destination address is considered a flow.

## Examples

The following is an example for the **class-map** command:

```
hostname(config)# access-list udp permit udp any any
hostname(config)# access-list tcp permit tcp any any
hostname(config)# access-list host_foo permit ip any 10.1.1.1 255.255.255.255

hostname(config)# class-map all_udp
hostname(config-cmap)# description "This class-map matches all UDP traffic"
hostname(config-cmap)# match access-list udp

hostname(config-cmap)# class-map all_tcp
hostname(config-cmap)# description "This class-map matches all TCP traffic"
hostname(config-cmap)# match access-list tcp

hostname(config-cmap)# class-map all_http
hostname(config-cmap)# description "This class-map matches all HTTP traffic"
hostname(config-cmap)# match port tcp eq http

hostname(config-cmap)# class-map to_server
hostname(config-cmap)# description "This class-map matches all traffic to server 10.1.1.1"
hostname(config-cmap)# match access-list host_foo
```

## Creating a Layer 3/4 Class Map for Management Traffic

For management traffic to the adaptive security appliance, you might want to perform actions specific to this kind of traffic. You can specify a management class map that can match an access list or TCP or UDP ports. The types of actions available for a management class map in the policy map are specialized for management traffic. See the [“Supported Features for Management Traffic” section on page 30-2](#).

### Detailed Steps

- Step 1** Create a class map by entering the following command:

```
hostname(config)# class-map type management class_map_name
hostname(config-cmap)#
```

Where *class\_map\_name* is a string up to 40 characters in length. The name “class-default” is reserved. All types of class maps use the same name space, so you cannot reuse a name already used by another type of class map. The CLI enters class-map configuration mode.

- Step 2** (Optional) Add a description to the class map by entering the following command:

```
hostname(config-cmap)# description string
```

- Step 3** Define the traffic to include in the class by matching one of the following characteristics. You can include only one **match** command in the class map.

- Access list—The class map matches traffic specified by an extended access list. If the adaptive security appliance is operating in transparent firewall mode, you can use an EtherType access list.

```
hostname(config-cmap)# match access-list access_list_name
```

For more information about creating access lists, see [Chapter 13, “Adding an Extended Access List,”](#) or [Chapter 14, “Adding an EtherType Access List.”](#)

For information about creating access lists with NAT, see the [“IP Addresses Used for Access Lists When You Use NAT” section on page 12-3](#).

- TCP or UDP destination ports—The class map matches a single port or a contiguous range of ports.

```
hostname(config-cmap)# match port {tcp | udp} {eq port_num | range port_num port_num}
```

**Tip** For applications that use multiple, non-contiguous ports, use the **match access-list** command and define an ACE to match each port.

For a list of ports you can specify, see the [“TCP and UDP Ports” section on page B-11](#).

For example, enter the following command to match TCP packets on port 80 (HTTP):

```
hostname(config-cmap)# match tcp eq 80
```

## Defining Actions (Layer 3/4 Policy Map)

This section describes how to associate actions with Layer 3/4 class maps by creating a Layer 3/4 policy map.

## Restrictions

The maximum number of policy maps is 64, but you can only apply one policy map per interface.

## Detailed Steps

- Step 1** Add the policy map by entering the following command:

```
hostname(config)# policy-map policy_map_name
```

The *policy\_map\_name* argument is the name of the policy map up to 40 characters in length. All types of policy maps use the same name space, so you cannot reuse a name already used by another type of policy map. The CLI enters policy-map configuration mode.

- Step 2** (Optional) Specify a description for the policy map:

```
hostname(config-pmap)# description text
```

- Step 3** Specify a previously configured Layer 3/4 class map using the following command:

```
hostname(config-pmap)# class class_map_name
```

where the *class\_map\_name* is the name of the class map you created earlier. See the [“Identifying Traffic \(Layer 3/4 Class Maps\)”](#) section on page 30-12 to add a class map.

- Step 4** Specify one or more actions for this class map. See the [“Supported Features for Through Traffic”](#) section on page 30-2.

**Note** If there is no **match default\_inspection\_traffic** command in a class map, then at most one **inspect** command is allowed to be configured under the class.

For QoS, you can configure a hierarchical policy map for the traffic shaping and priority queue features. See the [“Task Flow for Configuring Hierarchical Policy Maps for QoS Traffic Shaping”](#) section on page 30-11 for more information.

- Step 5** Repeat [Step 3](#) and [Step 4](#) for each class map you want to include in this policy map.

## Examples

The following is an example of a **policy-map** command for connection policy. It limits the number of connections allowed to the web server 10.1.1.1:

```
hostname(config)# access-list http-server permit tcp any host 10.1.1.1
hostname(config)# class-map http-server
hostname(config-cmap)# match access-list http-server

hostname(config)# policy-map global-policy
hostname(config-pmap)# description This policy map defines a policy concerning connection
to http server.
hostname(config-pmap)# class http-server
hostname(config-pmap-c)# set connection conn-max 256
```

The following example shows how multi-match works in a policy map:

```
hostname(config)# class-map inspection_default
hostname(config-cmap)# match default-inspection-traffic
hostname(config)# class-map http_traffic
```

```
hostname(config-cmap) # match port tcp eq 80

hostname(config) # policy-map outside_policy
hostname(config-pmap) # class inspection_default
hostname(config-pmap-c) # inspect http http_map
hostname(config-pmap-c) # inspect sip
hostname(config-pmap) # class http_traffic
hostname(config-pmap-c) # set connection timeout tcp 0:10:0
```

The following example shows how traffic matches the first available class map, and will not match any subsequent class maps that specify actions in the same feature domain:

```
hostname(config) # class-map telnet_traffic
hostname(config-cmap) # match port tcp eq 23
hostname(config) # class-map ftp_traffic
hostname(config-cmap) # match port tcp eq 21
hostname(config) # class-map tcp_traffic
hostname(config-cmap) # match port tcp range 1 65535
hostname(config) # class-map udp_traffic
hostname(config-cmap) # match port udp range 0 65535
hostname(config) # policy-map global_policy
hostname(config-pmap) # class telnet_traffic
hostname(config-pmap-c) # set connection timeout tcp 0:0:0
hostname(config-pmap-c) # set connection conn-max 100
hostname(config-pmap) # class ftp_traffic
hostname(config-pmap-c) # set connection timeout tcp 0:5:0
hostname(config-pmap-c) # set connection conn-max 50
hostname(config-pmap) # class tcp_traffic
hostname(config-pmap-c) # set connection timeout tcp 2:0:0
hostname(config-pmap-c) # set connection conn-max 2000
```

When a Telnet connection is initiated, it matches **class telnet\_traffic**. Similarly, if an FTP connection is initiated, it matches **class ftp\_traffic**. For any TCP connection other than Telnet and FTP, it will match **class tcp\_traffic**. Even though a Telnet or FTP connection can match **class tcp\_traffic**, the adaptive security appliance does not make this match because they previously matched other classes.

## Applying Actions to an Interface (Service Policy)

To activate the Layer 3/4 policy map, create a service policy that applies it to one or more interfaces or that applies it globally to all interfaces.

### Restrictions

You can only apply one global policy.

### Detailed Steps

- To create a service policy by associating a policy map with an interface, enter the following command:

```
hostname(config) # service-policy policy_map_name interface interface_name
```

- To create a service policy that applies to all interfaces that do not have a specific policy, enter the following command:

```
hostname(config) # service-policy policy_map_name global
```

By default, the configuration includes a global policy that matches all default application inspection traffic and applies inspection to the traffic globally. You can only apply one global policy, so if you want to alter the global policy, you need to either edit the default policy or disable it and apply a new one.

The default service policy includes the following command:

```
service-policy global_policy global
```

Examples

For example, the following command enables the inbound\_policy policy map on the outside interface:

```
hostname(config)# service-policy inbound_policy interface outside
```

The following commands disable the default global policy, and enables a new one called new\_global\_policy on all other adaptive security appliance interfaces:

```
hostname(config)# no service-policy global_policy global
hostname(config)# service-policy new_global_policy global
```

# Monitoring Modular Policy Framework

To monitor Modular Policy Framework, enter the following command:

| Command             | Purpose                                 |
|---------------------|-----------------------------------------|
| show service-policy | Displays the service policy statistics. |

# Configuration Examples for Modular Policy Framework

This section includes several Modular Policy Framework examples and includes the following topics:

- [Applying Inspection and QoS Policing to HTTP Traffic, page 30-19](#)
- [Applying Inspection to HTTP Traffic Globally, page 30-19](#)
- [Applying Inspection and Connection Limits to HTTP Traffic to Specific Servers, page 30-20](#)
- [Applying Inspection to HTTP Traffic with NAT, page 30-21](#)

## Applying Inspection and QoS Policing to HTTP Traffic

In this example (see [Figure 30-1](#)), any HTTP connection (TCP traffic on port 80) that enters or exits the adaptive security appliance through the outside interface is classified for HTTP inspection. Any HTTP traffic that exits the outside interface is classified for policing.

**Figure 30-1 HTTP Inspection and QoS Policing**

See the following commands for this example:

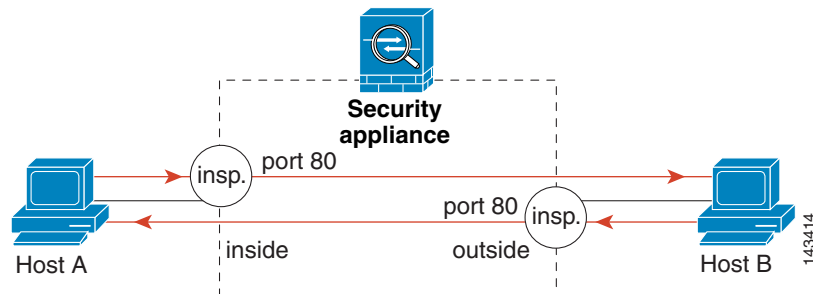

```
hostname(config)# class-map http_traffic
hostname(config-cmap)# match port tcp eq 80

hostname(config)# policy-map http_traffic_policy
hostname(config-pmap)# class http_traffic
hostname(config-pmap-c)# inspect http
hostname(config-pmap-c)# police output 250000
hostname(config)# service-policy http_traffic_policy interface outside
```

## Applying Inspection to HTTP Traffic Globally

In this example (see [Figure 30-2](#)), any HTTP connection (TCP traffic on port 80) that enters the adaptive security appliance through any interface is classified for HTTP inspection. Because the policy is a global policy, inspection occurs only as the traffic enters each interface.

**Figure 30-2 Global HTTP Inspection**

See the following commands for this example:

```
hostname(config)# class-map http_traffic
hostname(config-cmap)# match port tcp eq 80
```

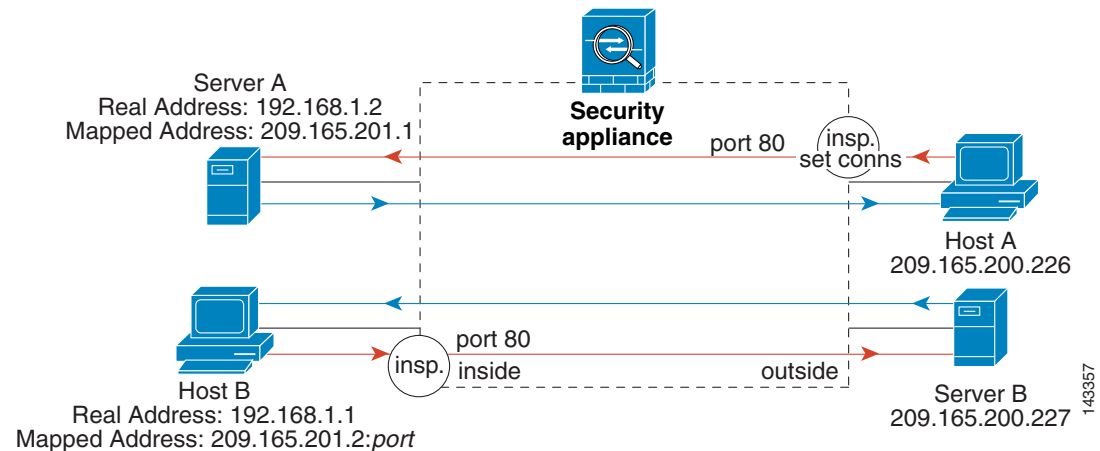

```
hostname(config)# policy-map http_traffic_policy
hostname(config-pmap)# class http_traffic
hostname(config-pmap-c)# inspect http
hostname(config)# service-policy http_traffic_policy global
```

## Applying Inspection and Connection Limits to HTTP Traffic to Specific Servers

In this example (see Figure 30-3), any HTTP connection destined for Server A (TCP traffic on port 80) that enters the adaptive security appliance through the outside interface is classified for HTTP inspection and maximum connection limits. Connections initiated from Server A to Host A does not match the access list in the class map, so it is not affected.

Any HTTP connection destined for Server B that enters the adaptive security appliance through the inside interface is classified for HTTP inspection. Connections initiated from Server B to Host B does not match the access list in the class map, so it is not affected.

**Figure 30-3** HTTP Inspection and Connection Limits to Specific Servers

See the following commands for this example:

```
hostname(config)# object network obj-192.168.1.2
hostname(config-network-object)# host 192.168.1.2
hostname(config-network-object)# nat (inside,outside) static 209.165.201.1
hostname(config)# object network obj-192.168.1.0
hostname(config-network-object)# subnet 192.168.1.0 255.255.255.0
hostname(config-network-object)# nat (inside,outside) dynamic 209.165.201.2
hostname(config)# access-list serverA extended permit tcp any host 209.165.201.1 eq 80
hostname(config)# access-list ServerB extended permit tcp any host 209.165.200.227 eq 80

hostname(config)# class-map http_serverA
hostname(config-cmap)# match access-list serverA
hostname(config)# class-map http_serverB
hostname(config-cmap)# match access-list serverB

hostname(config)# policy-map policy_serverA
hostname(config-pmap)# class http_serverA
hostname(config-pmap-c)# inspect http
hostname(config-pmap-c)# set connection conn-max 100
hostname(config)# policy-map policy_serverB
hostname(config-pmap)# class http_serverB
hostname(config-pmap-c)# inspect http
```

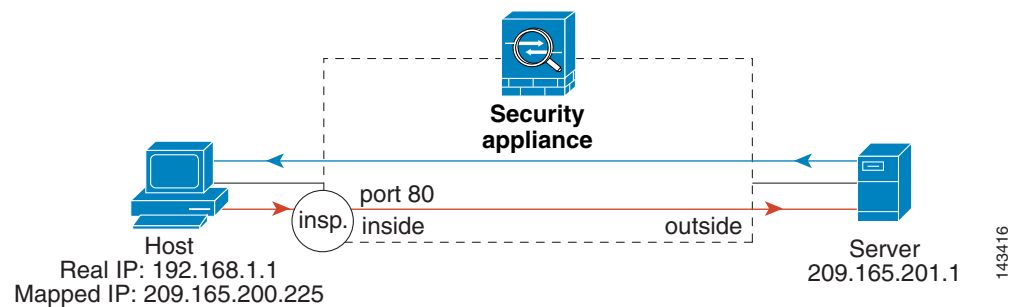

```
hostname(config)# service-policy policy_serverB interface inside
hostname(config)# service-policy policy_serverA interface outside
```

## Applying Inspection to HTTP Traffic with NAT

In this example, the Host on the inside network has two addresses: one is the real IP address 192.168.1.1, and the other is a mapped IP address used on the outside network, 209.165.200.225. Because the policy is applied to the inside interface, where the real address is used, then you must use the real IP address in the access list in the class map. If you applied it to the outside interface, you would use the mapped address.

**Figure 30-4 HTTP Inspection with NAT**

See the following commands for this example:

```
hostname(config)# static (inside,outside) 209.165.200.225 192.168.1.1
hostname(config)# access-list http_client extended permit tcp host 192.168.1.1 any eq 80

hostname(config)# class-map http_client
hostname(config-cmap)# match access-list http_client

hostname(config)# policy-map http_client
hostname(config-pmap)# class http_client
hostname(config-pmap-c)# inspect http

hostname(config)# service-policy http_client interface inside
```

## Feature History for Service Policies

Table 30-3 lists the release history for this feature.

**Table 30-3 Feature History for Service Policies**

| Feature Name                                                | Releases | Feature Information                                                                                                                                                                               |
|-------------------------------------------------------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Modular Policy Framework                                    | 7.0(1)   | Modular Policy Framework was introduced.                                                                                                                                                          |
| Management class map for use with RADIUS accounting traffic | 7.2(1)   | The management class map was introduced for use with RADIUS accounting traffic. The following commands were introduced: <b>class-map type management</b> , and <b>inspect radius-accounting</b> . |

**Table 30-3** *Feature History for Service Policies (continued)*

| Feature Name                                                         | Releases | Feature Information                                                                                                                                                                                                       |
|----------------------------------------------------------------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inspection policy maps                                               | 7.2(1)   | The inspection policy map was introduced. The following command was introduced: <b>class-map type inspect</b> .                                                                                                           |
| Regular expressions and policy maps                                  | 7.2(1)   | Regular expressions and policy maps were introduced to be used under inspection policy maps. The following commands were introduced: <b>class-map type regex</b> , <b>regex</b> , <b>match regex</b> .                    |
| Match any for inspection policy maps                                 | 8.0(2)   | The <b>match any</b> keyword was introduced for use with inspection policy maps: traffic can match one or more criteria to match the class map. Formerly, only <b>match all</b> was available.                            |
| Maximum connections and embryonic connections for management traffic | 8.0(2)   | The <b>set connection</b> command is now available for a Layer 3/4 management class map, for to-the-security appliance management traffic. Only the <b>conn-max</b> and <b>embryonic-conn-max</b> keywords are available. |

# CHAPTER 31

## Configuring Special Actions for Application Inspections (Inspection Policy Map)

---

Modular Policy Framework lets you configure special actions for many application inspections. When you enable an inspection engine in the Layer 3/4 policy map, you can also optionally enable actions as defined in an *inspection policy map*. When the inspection policy map matches traffic within the Layer 3/4 class map for which you have defined an inspection action, then that subset of traffic will be acted upon as specified (for example, dropped or rate-limited).

This chapter includes the following sections:

- [Information About Inspection Policy Maps, page 31-1](#)
- [Default Inspection Policy Maps, page 31-2](#)
- [Defining Actions in an Inspection Policy Map, page 31-2](#)
- [Identifying Traffic in an Inspection Class Map, page 31-5](#)
- [Where to Go Next, page 31-6](#)

## Information About Inspection Policy Maps

See the [“Configuring Application Layer Protocol Inspection” section on page 38-6](#) for a list of applications that support inspection policy maps.

An inspection policy map consists of one or more of the following elements. The exact options available for an inspection policy map depends on the application.

- Traffic matching command—You can define a traffic matching command directly in the inspection policy map to match application traffic to criteria specific to the application, such as a URL string, for which you then enable actions.
  - Some traffic matching commands can specify regular expressions to match text inside a packet. Be sure to create and test the regular expressions before you configure the policy map, either singly or grouped together in a regular expression class map.
- Inspection class map—(Not available for all applications. See the CLI help for a list of supported applications.) An inspection class map includes traffic matching commands that match application traffic with criteria specific to the application, such as a URL string. You then identify the class map in the policy map and enable actions. The difference between creating a class map and defining the traffic match directly in the inspection policy map is that you can create more complex match criteria and you can reuse class maps.

- Some traffic matching commands can specify regular expressions to match text inside a packet. Be sure to create and test the regular expressions before you configure the policy map, either singly or grouped together in a regular expression class map.
- Parameters—Parameters affect the behavior of the inspection engine.

## Default Inspection Policy Maps

The default inspection policy map configuration includes the following commands, which sets the maximum message length for DNS packets to be 512 bytes:

```
policy-map type inspect dns preset_dns_map
  parameters
    message-length maximum 512
```

### Note

There are other default inspection policy maps such as **policy-map type inspect esmtp \_default\_esmtp\_map**. These default policy maps are created implicitly by the command **inspect protocol**. For example, **inspect esmtp** implicitly uses the policy map “\_default\_esmtp\_map.” All the default policy maps can be shown by using the **show running-config all policy-map** command.

## Defining Actions in an Inspection Policy Map

When you enable an inspection engine in the Layer 3/4 policy map, you can also optionally enable actions as defined in an inspection policy map.

### Restrictions

You can specify multiple **class** or **match** commands in the policy map.

If a packet matches multiple different **match** or **class** commands, then the order in which the adaptive security appliance applies the actions is determined by internal adaptive security appliance rules, and not by the order they are added to the policy map. The internal rules are determined by the application type and the logical progression of parsing a packet, and are not user-configurable. For example for HTTP traffic, parsing a Request Method field precedes parsing the Header Host Length field; an action for the Request Method field occurs before the action for the Header Host Length field. For example, the following match commands can be entered in any order, but the **match request method get** command is matched first.

```
match request header host length gt 100
  reset
match request method get
  log
```

If an action drops a packet, then no further actions are performed in the inspection policy map. For example, if the first action is to reset the connection, then it will never match any further **match** or **class** commands. If the first action is to log the packet, then a second action, such as resetting the connection, can occur. (You can configure both the **reset** (or **drop-connection**, and so on.) and the **log** action for the same **match** or **class** command, in which case the packet is logged before it is reset for a given match.)

If a packet matches multiple **match** or **class** commands that are the same, then they are matched in the order they appear in the policy map. For example, for a packet with the header length of 1001, it will match the first command below, and be logged, and then will match the second command and be reset. If you reverse the order of the two **match** commands, then the packet will be dropped and the connection reset before it can match the second **match** command; it will never be logged.

```
match request header length gt 100
    log
match request header length gt 1000
    reset
```

A class map is determined to be the same type as another class map or **match** command based on the lowest priority **match** command in the class map (the priority is based on the internal rules). If a class map has the same type of lowest priority **match** command as another class map, then the class maps are matched according to the order they are added to the policy map. If the lowest priority command for each class map is different, then the class map with the higher priority **match** command is matched first. For example, the following three class maps contain two types of **match** commands: **match request-cmd** (higher priority) and **match filename** (lower priority). The ftp3 class map includes both commands, but it is ranked according to the lowest priority command, **match filename**. The ftp1 class map includes the highest priority command, so it is matched first, regardless of the order in the policy map. The ftp3 class map is ranked as being of the same priority as the ftp2 class map, which also contains the **match filename** command. They are matched according to the order in the policy map: ftp3 and then ftp2.

```
class-map type inspect ftp match-all ftp1
    match request-cmd get
class-map type inspect ftp match-all ftp2
    match filename regex abc
class-map type inspect ftp match-all ftp3
    match request-cmd get
    match filename regex abc

policy-map type inspect ftp ftp
    class ftp3
        log
    class ftp2
        log
    class ftp1
        log
```

## Detailed Steps

**Step 1** (Optional) Create an inspection class map according to the “[Identifying Traffic in an Inspection Class Map](#)” section on page 31-5. Alternatively, you can identify the traffic directly within the policy map.

**Step 2** To create the inspection policy map, enter the following command:

```
hostname(config)# policy-map type inspect application policy_map_name
hostname(config-pmap)#
```

See the “[Configuring Application Layer Protocol Inspection](#)” section on page 38-6 for a list of applications that support inspection policy maps.

The *policy\_map\_name* argument is the name of the policy map up to 40 characters in length. All types of policy maps use the same name space, so you cannot reuse a name already used by another type of policy map. The CLI enters policy-map configuration mode.

**Step 3** To apply actions to matching traffic, perform the following steps.

**Note**

For information about including multiple **class** or **match** commands, see the [“Restrictions” section on page 31-2](#).

- a. Specify the traffic on which you want to perform actions using one of the following methods:
  - Specify the inspection class map that you created in the [“Identifying Traffic in an Inspection Class Map” section on page 31-5](#) by entering the following command:
- b. Specify the action you want to perform on the matching traffic by entering the following command:

```
hostname(config-pmap)# class class_map_name
hostname(config-pmap-c)#
```

Not all applications support inspection class maps.

- Specify traffic directly in the policy map using one of the **match** commands described for each application in the applicable inspection chapter. If you use a **match not** command, then any traffic that matches the criterion in the **match not** command does not have the action applied.

```
hostname(config-pmap-c)# {[drop [send-protocol-error] |
drop-connection [send-protocol-error] | mask | reset] [log] | rate-limit message_rate}
```

Not all options are available for each application. Other actions specific to the application might also be available. See the appropriate inspection chapter for the exact options available.

The **drop** keyword drops all packets that match.

The **send-protocol-error** keyword sends a protocol error message.

The **drop-connection** keyword drops the packet and closes the connection.

The **mask** keyword masks out the matching portion of the packet.

The **reset** keyword drops the packet, closes the connection, and sends a TCP reset to the server and/or client.

The **log** keyword, which you can use alone or with one of the other keywords, sends a system log message.

The **rate-limit** *message\_rate* argument limits the rate of messages.

- Step 4** To configure parameters that affect the inspection engine, enter the following command:

```
hostname(config-pmap)# parameters
hostname(config-pmap-p)#
```

The CLI enters parameters configuration mode. For the parameters available for each application, see the appropriate inspection chapter.

## Examples

The following is an example of an HTTP inspection policy map and the related class maps. This policy map is activated by the Layer 3/4 policy map, which is enabled by the service policy.

```
hostname(config)# regex url_example example\.com
hostname(config)# regex url_example2 example2\.com
hostname(config)# class-map type regex match-any URLs
hostname(config-cmap)# match regex url_example
hostname(config-cmap)# match regex url_example2

hostname(config-cmap)# class-map type inspect http match-all http-traffic
```

```

hostname(config-cmap)# match req-resp content-type mismatch
hostname(config-cmap)# match request body length gt 1000
hostname(config-cmap)# match not request uri regex class URLs

hostname(config-cmap)# policy-map type inspect http http-map1
hostname(config-pmap)# class http-traffic
hostname(config-pmap-c)# drop-connection log
hostname(config-pmap-c)# match req-resp content-type mismatch
hostname(config-pmap-c)# reset log
hostname(config-pmap-c)# parameters
hostname(config-pmap-p)# protocol-violation action log

hostname(config-pmap-p)# policy-map test
hostname(config-pmap)# class test (a Layer 3/4 class map not shown)
hostname(config-pmap-c)# inspect http http-map1

hostname(config-pmap-c)# service-policy test interface outside

```

## Identifying Traffic in an Inspection Class Map

This type of class map allows you to match criteria that is specific to an application. For example, for DNS traffic, you can match the domain name in a DNS query.

A class map groups multiple traffic matches (in a match-all class map), or lets you match any of a list of matches (in a match-any class map). The difference between creating a class map and defining the traffic match directly in the inspection policy map is that the class map lets you group multiple match commands, and you can reuse class maps. For the traffic that you identify in this class map, you can specify actions such as dropping, resetting, and/or logging the connection in the inspection policy map. If you want to perform different actions on different types of traffic, you should identify the traffic directly in the policy map.

### Restrictions

Not all applications support inspection class maps. See the CLI help for **class-map type inspect** for a list of supported applications.

### Detailed Steps

**Step 1** (Optional) If you want to match based on a regular expression, see the [“Creating a Regular Expression” section on page 11-12](#) and the [“Creating a Regular Expression Class Map” section on page 11-15](#).

**Step 2** Create a class map by entering the following command:

```

hostname(config)# class-map type inspect application [match-all | match-any]
class_map_name
hostname(config-cmap)#

```

Where the *application* is the application you want to inspect. For supported applications, see the CLI help for a list of supported applications or see [Chapter 38, “Getting Started With Application Layer Protocol Inspection.”](#)

The *class\_map\_name* argument is the name of the class map up to 40 characters in length.

The **match-all** keyword is the default, and specifies that traffic must match all criteria to match the class map.

The **match-any** keyword specifies that the traffic matches the class map if it matches at least one of the criteria.

The CLI enters class-map configuration mode, where you can enter one or more **match** commands.

**Step 3** (Optional) To add a description to the class map, enter the following command:

```
hostname(config-cmap) # description string
```

**Step 4** Define the traffic to include in the class by entering one or more **match** commands available for your application.

To specify traffic that should not match the class map, use the **match not** command. For example, if the **match not** command specifies the string “example.com,” then any traffic that includes “example.com” does not match the class map.

To see the **match** commands available for each application, see the appropriate inspection chapter.

---

## Examples

The following example creates an HTTP class map that must match all criteria:

```
hostname(config-cmap) # class-map type inspect http match-all http-traffic
hostname(config-cmap) # match req-resp content-type mismatch
hostname(config-cmap) # match request body length gt 1000
hostname(config-cmap) # match not request uri regex class URLs
```

The following example creates an HTTP class map that can match any of the criteria:

```
hostname(config-cmap) # class-map type inspect http match-any monitor-http
hostname(config-cmap) # match request method get
hostname(config-cmap) # match request method put
hostname(config-cmap) # match request method post
```

## Where to Go Next

To use an inspection policy, see [Chapter 30, “Configuring a Service Policy Using the Modular Policy Framework.”](#)

## **PART 7**

### **Configuring Access Control**

# CHAPTER 32

## Configuring Access Rules

---

This chapter describes how to control network access through the adaptive security appliance using access rules, and it includes the following sections:

- [Information About Access Rules, page 32-1](#)
- [Licensing Requirements for Access Rules, page 32-6](#)
- [Prerequisites, page 32-6](#)
- [Guidelines and Limitations, page 32-6](#)
- [Default Settings, page 32-7](#)
- [Configuring Access Rules, page 32-7](#)
- [Monitoring Access Rules, page 32-8](#)
- [Configuration Examples for Permitting or Denying Network Access, page 32-8](#)
- [Feature History for Access Rules, page 32-9](#)

### Note

You use access rules to control network access in both routed and transparent firewall modes. In transparent mode, you can use both access rules (for Layer 3 traffic) and EtherType rules (for Layer 2 traffic).

To access the adaptive security appliance interface for management access, you do not also need an access rule allowing the host IP address. You only need to configure management access according to [Chapter 34, “Configuring Management Access.”](#)

---

## Information About Access Rules

You create an access rule by applying an extended or EtherType access list to an interface or globally for all interfaces. You can use access rules in routed and transparent firewall mode to control IP traffic. An access rule permits or denies traffic based on the protocol, a source and destination IP address or network, and optionally the source and destination ports.

For transparent mode only, an EtherType rule controls network access for non-IP traffic. An EtherType rule permits or denies traffic based on the EtherType.

This section includes the following topics:

- [General Information About Rules, page 32-2](#)
- [Information About Extended Access Rules, page 32-4](#)

- [Information About EtherType Rules, page 32-5](#)

## General Information About Rules

This section describes information for both access rules and EtherType rules, and it includes the following topics:

- [Implicit Permits, page 32-2](#)
- [Using Access Rules and EtherType Rules on the Same Interface, page 32-2](#)
- [Inbound and Outbound Rules, page 32-2](#)
- [Using Global Access Rules, page 32-4](#)

### Implicit Permits

For routed mode, the following types of traffic are allowed through by default:

- IPv4 traffic from a higher security interface to a lower security interface.
- IPv6 traffic from a higher security interface to a lower security interface.

For transparent mode, the following types of traffic are allowed through by default:

- IPv4 traffic from a higher security interface to a lower security interface.
- IPv6 traffic from a higher security interface to a lower security interface.
- ARPs in both directions.

---

**Note** ARP traffic can be controlled by ARP inspection, but cannot be controlled by an access rule.

---

- BPDUs in both directions.

For other traffic, you need to use either an extended access rule (IPv4), an IPv6 access rule (IPv6), or an EtherType rule (non-IPv4/IPv6).

### Using Access Rules and EtherType Rules on the Same Interface

You can apply one access rule and one EtherType rule to each direction of an interface.

### Inbound and Outbound Rules

The adaptive security appliance supports two types of access lists:

- Inbound—Inbound access lists apply to traffic as it enters an interface.
- Outbound—Outbound access lists apply to traffic as it exits an interface.

**Note**

---

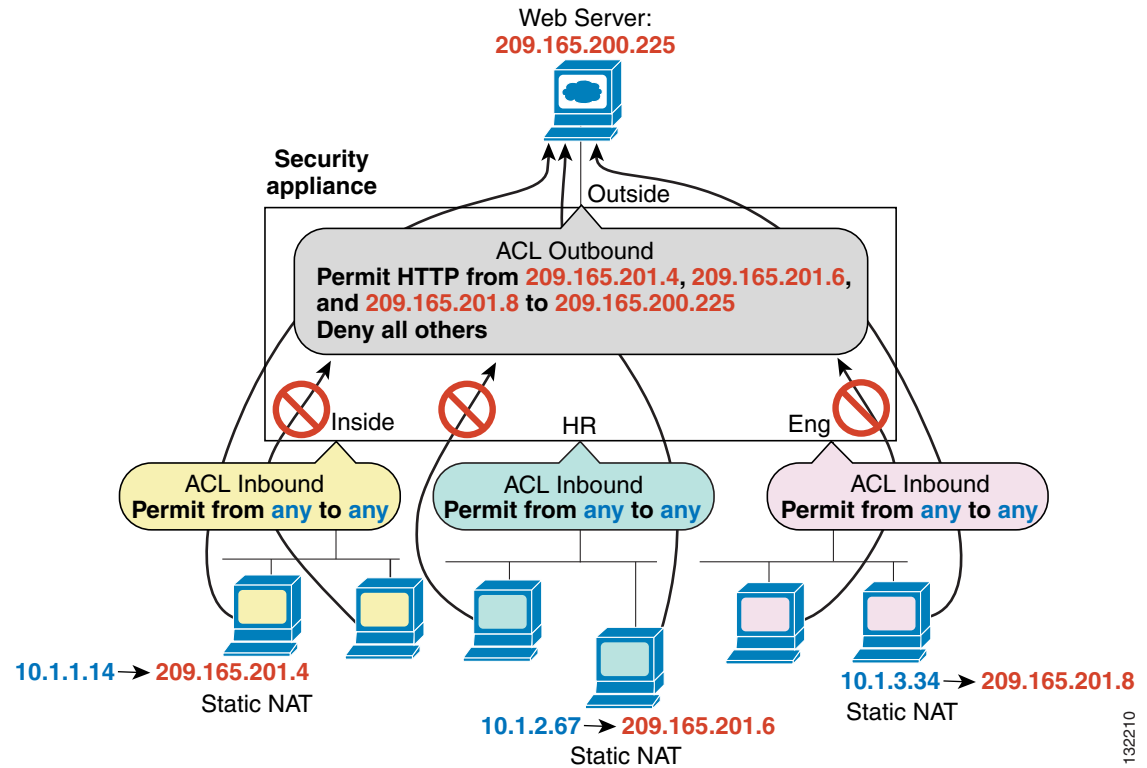

“Inbound” and “outbound” refer to the application of an access list on an interface, either to traffic entering the adaptive security appliance on an interface or traffic exiting the adaptive security appliance on an interface. These terms do not refer to the movement of traffic from a lower security interface to a higher security interface, commonly known as inbound, or from a higher to lower interface, commonly known as outbound.

---

An inbound access list can bind an access list to a specific interface or apply a global rule on all interfaces. For more information about global rules, see the [“Using Global Access Rules”](#) section on page 32-4.

An outbound access list is useful, for example, if you want to allow only certain hosts on the inside networks to access a web server on the outside network. Rather than creating multiple inbound access lists to restrict access, you can create a single outbound access list that allows only the specified hosts. (See [Figure 32-1](#).) The outbound access list prevents any other hosts from reaching the outside network.

**Figure 32-1 Outbound Access List**

See the following commands for this example:

```
hostname(config)# access-list OUTSIDE extended permit tcp host 209.165.201.4
host 209.165.200.225 eq www
hostname(config)# access-list OUTSIDE extended permit tcp host 209.165.201.6
host 209.165.200.225 eq www
hostname(config)# access-list OUTSIDE extended permit tcp host 209.165.201.8
host 209.165.200.225 eq www
hostname(config)# access-group OUTSIDE out interface outside
```

## Using Global Access Rules

Global access rules allow you to apply a global rule to ingress traffic without the need to specify an interface to which the rule must be applied. Using global access rules provides the following benefits:

- When migrating to the adaptive security appliance from a competitor appliance, you can maintain a global access rule policy instead of needing to apply an interface-specific policy on each interface.
- Global access control policies are not replicated on each interface, so they save memory space.
- Global access rules provides flexibility in defining a security policy. You do not need to specify which interface a packet comes in on, as long as it matches the source and destination IP addresses.
- Global access rules use the same mtrie and stride tree as interface-specific access rules, so scalability and performance for global rules are the same as for interface-specific rules.

You can configure global access rules in conjunction with interface access rules, in which case, the specific interface access rules are always processed before the general global access rules.

## Information About Extended Access Rules

This section describes information about extended access rules and includes the following topics:

- [Access Rules for Returning Traffic, page 32-4](#)
- [Allowing Broadcast and Multicast Traffic through the Transparent Firewall Using Access Rules, page 32-4](#)
- [Management Access Rules, page 32-5](#)

## Access Rules for Returning Traffic

For TCP and UDP connections for both routed and transparent mode, you do not need an access rule to allow returning traffic because the adaptive security appliance allows all returning traffic for established, bidirectional connections.

For connectionless protocols such as ICMP, however, the adaptive security appliance establishes unidirectional sessions, so you either need access rules to allow ICMP in both directions (by applying access lists to the source and destination interfaces), or you need to enable the ICMP inspection engine. The ICMP inspection engine treats ICMP sessions as bidirectional connections. To control ping, specify **echo-reply (0)** (adaptive security appliance to host) or **echo (8)** (host to adaptive security appliance).

## Allowing Broadcast and Multicast Traffic through the Transparent Firewall Using Access Rules

In routed firewall mode, broadcast and multicast traffic is blocked even if you allow it in an access rule, including unsupported dynamic routing protocols and DHCP (unless you configure DHCP relay). Transparent firewall mode can allow any IP traffic through. This feature is especially useful in multiple context mode, which does not allow dynamic routing, for example.

### Note

Because these special types of traffic are connectionless, you need to apply an extended access list to both interfaces, so returning traffic is allowed through.

Table 32-1 lists common traffic types that you can allow through the transparent firewall.

**Table 32-1**      *Transparent Firewall Special Traffic*

| Traffic Type      | Protocol or Port                                 | Notes                                                                                           |
|-------------------|--------------------------------------------------|-------------------------------------------------------------------------------------------------|
| DHCP              | UDP ports 67 and 68                              | If you enable the DHCP server, then the adaptive security appliance does not pass DHCP packets. |
| EIGRP             | Protocol 88                                      | —                                                                                               |
| OSPF              | Protocol 89                                      | —                                                                                               |
| Multicast streams | The UDP ports vary depending on the application. | Multicast streams are always destined to a Class D address (224.0.0.0 to 239.x.x.x).            |
| RIP (v1 or v2)    | UDP port 520                                     | —                                                                                               |

## Management Access Rules

You can configure access rules that control management traffic destined to the adaptive security appliance. Access control rules for to-the-box management traffic (defined by such commands as **http**, **ssh**, or **telnet**) have higher precedence than an management access rule applied with the **control-plane** option. Therefore, such permitted management traffic will be allowed to come in even if explicitly denied by the to-the-box access list.

## Information About EtherType Rules

This section describes EtherType rules and includes the following topics:

- [Supported EtherTypes, page 32-5](#)
- [Access Rules for Returning Traffic, page 32-5](#)
- [Allowing MPLS, page 32-6](#)

## Supported EtherTypes

- An EtherType rule controls any EtherType identified by a 16-bit hexadecimal number.
- EtherType rules support Ethernet V2 frames.
- 802.3-formatted frames are not handled by the rule because they use a length field as opposed to a type field.
- BPDUs, which are permitted by default, are the only exception: they are SNAP-encapsulated, and the adaptive security appliance is designed to specifically handle BPDUs.
- The adaptive security appliance receives trunk port (Cisco proprietary) BPDUs. Trunk BPDUs have VLAN information inside the payload, so the adaptive security appliance modifies the payload with the outgoing VLAN if you allow BPDUs.

## Access Rules for Returning Traffic

Because EtherTypes are connectionless, you need to apply the rule to both interfaces if you want traffic to pass in both directions.

## Allowing MPLS

If you allow MPLS, ensure that Label Distribution Protocol and Tag Distribution Protocol TCP connections are established through the adaptive security appliance by configuring both MPLS routers connected to the adaptive security appliance to use the IP address on the adaptive security appliance interface as the router-id for LDP or TDP sessions. (LDP and TDP allow MPLS routers to negotiate the labels (addresses) used to forward packets.)

On Cisco IOS routers, enter the appropriate command for your protocol, LDP or TDP. The *interface* is the interface connected to the adaptive security appliance.

```
hostname(config)# mpls ldp router-id interface force
```

Or

```
hostname(config)# tag-switching tdp router-id interface force
```

## Licensing Requirements for Access Rules

The following table shows the licensing requirements for this feature:

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Prerequisites

Before you can create an access rule, create the access list. See [Chapter 13, “Adding an Extended Access List,”](#) and [Chapter 14, “Adding an EtherType Access List,”](#) for more information.

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported in routed and transparent firewall modes.

### IPv6 Guidelines

Supports IPv6

### Per-User Access List Guidelines

- If there is no per-user access list associated with a packet, the interface access rule is applied.
- The per-user access list uses the value in the **timeout uauth** command, but it can be overridden by the AAA per-user session timeout value.

- If traffic is denied because of a per-user access list, syslog message 109025 is logged. If traffic is permitted, no syslog message is generated. The **log** option in the per-user access list has no effect.

#### Additional Guidelines and Limitations

To access the adaptive security appliance interface for management access, you do not need an access list allowing the host IP address. You only need to configure management access by following the instructions in [Chapter 34, “Configuring Management Access.”](#)

## Default Settings

See the “Implicit Permits” section on page 32-2.

## Configuring Access Rules

To apply an access rule, perform the following steps.

| Command                                                                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>access-group access_list {{in   out} interface interface_name [per-user-override   control-plane]   global}</pre> <p><b>Example:</b></p> <pre>hostname(config)# access-group acl_out in interface outside</pre> | <p>Binds an access list to an interface or applies it globally.</p> <p><b>Note</b> The <b>access-group</b> command cannot reference empty access lists or access lists that contain only a remark.</p> <p>The <b>in</b> keyword applies the access list to the traffic on the specified interface. The <b>out</b> keyword applies the access list to the outbound traffic.</p> <p>The <b>per-user-override</b> keyword (for inbound access lists only) allows dynamic user access lists that are downloaded for user authorization to override the access list assigned to the interface. For example, if the interface access list denies all traffic from 10.0.0.0, but the dynamic access list permits all traffic from 10.0.0.0, then the dynamic access list overrides the interface access list for that user. See the “<a href="#">Configuring RADIUS Authorization</a>” section on page 35-10 for more information about per-user access lists. See also the “<a href="#">Per-User Access List Guidelines</a>” section on page 32-6.</p> <p>The <b>control-plane</b> keyword specifies if the rule is for to-the-box traffic.</p> <p>The <b>global</b> keyword applies the access list to the inbound direction of all interfaces.</p> |

### Examples

The following example shows how to use the **access-group** command:

```
hostname(config)# access-list acl_out permit tcp any host 209.165.201.3 eq 80
hostname(config)# access-group acl_out in interface outside
```

The **access-list** command lets any host access the global address using port 80. The **access-group** command specifies that the **access-list** command applies to traffic entering the outside interface.

# Monitoring Access Rules

To monitor network access, perform one of the following tasks:

| Command                                       | Purpose                                                   |
|-----------------------------------------------|-----------------------------------------------------------|
| <code>show running-config access-group</code> | Displays the current access list bound to the interfaces. |

## Configuration Examples for Permitting or Denying Network Access

This section includes typical configuration examples for permitting or denying network access.

The following example illustrates the commands required to enable access to an inside web server with the IP address 209.165.201.12. (This IP address is the real address, not the visible on the outside interface after NAT.)

```
hostname(config)# access-list ACL_OUT extended permit tcp any host 209.165.201.12 eq www
hostname(config)# access-group ACL_OUT in interface outside
```

The following example allows all hosts to communicate between the **inside** and **hr** networks but only specific hosts to access the outside network:

```
hostname(config)# access-list ANY extended permit ip any any
hostname(config)# access-list OUT extended permit ip host 209.168.200.3 any
hostname(config)# access-list OUT extended permit ip host 209.168.200.4 any

hostname(config)# access-group ANY in interface inside
hostname(config)# access-group ANY in interface hr
hostname(config)# access-group OUT out interface outside
```

For example, the following sample access list allows common EtherTypes originating on the inside interface:

```
hostname(config)# access-list ETHER ethertype permit ipx
hostname(config)# access-list ETHER ethertype permit mpls-unicast
hostname(config)# access-group ETHER in interface inside
```

The following example allows some EtherTypes through the adaptive security appliance, but it denies all others:

```
hostname(config)# access-list ETHER ethertype permit 0x1234
hostname(config)# access-list ETHER ethertype permit mpls-unicast
hostname(config)# access-group ETHER in interface inside
hostname(config)# access-group ETHER in interface outside
```

The following example denies traffic with EtherType 0x1256 but allows all others on both interfaces:

```
hostname(config)# access-list nonIP ethertype deny 1256
hostname(config)# access-list nonIP ethertype permit any
hostname(config)# access-group ETHER in interface inside
hostname(config)# access-group ETHER in interface outside
```

The following example uses object groups to permit specific traffic on the inside interface:

```
!
hostname (config)# object-group service myaclog
```

```

hostname (config-service)# service-object tcp source range 2000 3000
hostname (config-service)# service-object tcp source range 3000 3010 destination$
hostname (config-service)# service-object ipsec
hostname (config-service)# service-object udp destination range 1002 1006
hostname (config-service)# service-object icmp echo

hostname(config)# access-list outsideacl extended permit object-group myaclog interface
inside any

```

## Feature History for Access Rules

Table 32-2 lists each feature change and the platform release in which it was implemented.

**Table 32-2**      *Feature History for Access Rules*

| Feature Name            | Platform Releases | Feature Information                                                                                                                              |

# CHAPTER 33

## Configuring AAA Servers and the Local Database

---

This chapter describes support for AAA (pronounced “triple A”) and how to configure AAA servers and the local database.

The chapter includes the following sections:

- [AAA Overview, page 33-1](#)
- [AAA Server and Local Database Support, page 33-3](#)
- [Configuring the Local Database, page 33-8](#)
- [Identifying AAA Server Groups and Servers, page 33-11](#)
- [Configuring an LDAP Server, page 33-15](#)
- [Using Certificates and User Login Credentials, page 33-20](#)
- [Differentiating User Roles Using AAA, page 33-21](#)
- [AAA Servers Monitoring Commands, page 33-23](#)
- [Additional References, page 33-24](#)
- [Feature History for AAA Servers, page 33-25](#)

### AAA Overview

AAA enables the adaptive security appliance to determine who the user is (authentication), what the user can do (authorization), and what the user did (accounting).

AAA provides an extra level of protection and control for user access than using access lists alone. For example, you can create an access list allowing all outside users to access Telnet on a server on the DMZ network. If you want only some users to access the server and you might not always know IP addresses of these users, you can enable AAA to allow only authenticated and/or authorized users to connect through the adaptive security appliance. (The Telnet server enforces authentication, too; the adaptive security appliance prevents unauthorized users from attempting to access the server.)

You can use authentication alone or with authorization and accounting. Authorization always requires a user to be authenticated first. You can use accounting alone, or with authentication and authorization.

This section includes the following topics:

- [About Authentication, page 33-2](#)
- [About Authorization, page 33-2](#)
- [About Accounting, page 33-3](#)

## About Authentication

Authentication controls access by requiring valid user credentials, which are usually a username and password. You can configure the adaptive security appliance to authenticate the following items:

- All administrative connections to the adaptive security appliance including the following sessions:
  - Telnet
  - SSH
  - Serial console
  - ASDM using HTTPS
  - VPN management access
- The **enable** command
- Network access
- VPN access

## About Authorization

Authorization controls access *per user* after users are authenticated. You can configure the adaptive security appliance to authorize the following items:

- Management commands
- Network access
- VPN access

Authorization controls the services and commands that are available to each authenticated user. If you did not enable authorization, authentication alone would provide the same access to services for all authenticated users.

If you need the control that authorization provides, you can configure a broad authentication rule, and then have a detailed authorization configuration. For example, you can authenticate inside users who attempt to access any server on the outside network and then limit the outside servers that a particular user can access using authorization.

The adaptive security appliance caches the first 16 authorization requests per user, so if the user accesses the same services during the current authentication session, the adaptive security appliance does not resend the request to the authorization server.

## About Accounting

Accounting tracks traffic that passes through the adaptive security appliance, enabling you to have a record of user activity. If you enable authentication for that traffic, you can account for traffic per user. If you do not authenticate the traffic, you can account for traffic per IP address. Accounting information includes session start and stop times, username, the number of bytes that pass through the adaptive security appliance for the session, the service used, and the duration of each session.

## AAA Server and Local Database Support

The adaptive security appliance supports a variety of AAA server types and a local database that is stored on the adaptive security appliance. This section describes support for each AAA server type and the local database, and includes the following topics:

- [Summary of Support, page 33-3](#)
- [RADIUS Server Support, page 33-4](#)
- [TACACS+ Server Support, page 33-5](#)
- [RSA/SDI Server Support, page 33-5](#)
- [NT Server Support, page 33-6](#)
- [Kerberos Server Support, page 33-6](#)
- [LDAP Server Support, page 33-7](#)
- [HTTP Forms Authentication for Clientless SSL VPN, page 33-7](#)
- [Local Database Support, page 33-7](#)

## Summary of Support

[Table 33-1](#) summarizes the support for each AAA service by each AAA server type, including the local database. For more information about support for a specific AAA server type, see the topics following the table.

**Table 33-1 Summary of AAA Support**

| AAA Service                 | Database Type    |                  |         |                  |     |          |      |                  |
|-----------------------------|------------------|------------------|---------|------------------|-----|----------|------|------------------|
|                             | Local            | RADIUS           | TACACS+ | SDI (RSA)        | NT  | Kerberos | LDAP | HTTP Form        |
| <b>Authentication of...</b> |                  |                  |         |                  |     |          |      |                  |
| VPN users <sup>1</sup>      | Yes              | Yes              | Yes     | Yes              | Yes | Yes      | Yes  | Yes <sup>2</sup> |
| Firewall sessions           | Yes              | Yes              | Yes     | Yes              | Yes | Yes      | Yes  | No               |
| Administrators              | Yes              | Yes              | Yes     | Yes <sup>3</sup> | Yes | Yes      | Yes  | No               |
| <b>Authorization of...</b>  |                  |                  |         |                  |     |          |      |                  |
| VPN users                   | Yes              | Yes              | No      | No               | No  | No       | Yes  | No               |
| Firewall sessions           | No               | Yes <sup>4</sup> | Yes     | No               | No  | No       | No   | No               |
| Administrators              | Yes <sup>5</sup> | No               | Yes     | No               | No  | No       | No   | No               |
| <b>Accounting of...</b>     |                  |                  |         |                  |     |          |      |                  |

**Table 33-1** Summary of AAA Support (continued)

| AAA Service       | Database Type |                  |         |           |    |          |      |           |
|-------------------|---------------|------------------|---------|-----------|----|----------|------|-----------|
|                   | Local         | RADIUS           | TACACS+ | SDI (RSA) | NT | Kerberos | LDAP | HTTP Form |
| VPN connections   | No            | Yes              | Yes     | No        | No | No       | No   | No        |
| Firewall sessions | No            | Yes              | Yes     | No        | No | No       | No   | No        |
| Administrators    | No            | Yes <sup>6</sup> | Yes     | No        | No | No       | No   | No        |

1. For SSL VPN connections, either PAP or MS-CHAPv2 can be used.
2. HTTP Form protocol supports both authentication and single sign-on operations for clientless SSL VPN users sessions only.
3. RSA/SDI is supported for ASDM HTTP administrative access with ASA5500 software version 8.2(1) or later.
4. For firewall sessions, RADIUS authorization is supported with user-specific access lists only, which are received or specified in a RADIUS authentication response.
5. Local command authorization is supported by privilege level only.
6. Command accounting is available for TACACS+ only.

**Note**

In addition to the native protocol authentication listed in table Table 1-1, the adaptive security appliance supports proxying authentication. For example, the adaptive security appliance can proxy to an RSA/SDI and/or LDAP server via a RADIUS server. Authentication via digital certificates and/or digital certificates with the AAA combinations listed in the table are also supported.

## RADIUS Server Support

The adaptive security appliance supports the following RADIUS servers for AAA, in addition to the one available on the adaptive security appliance itself:

- Cisco Secure ACS 3.2, 4.0, 4.1
- RSA RADIUS in RSA Authentication Manager 5.2 and 6.1

## Authentication Methods

The adaptive security appliance supports the following authentication methods with RADIUS:

- PAP—For all connection types.
- CHAP and MS-CHAPv1—For L2TP-over-IPsec connections.
- MS-CHAPv2—For L2TP-over-IPsec connections, and for regular IPsec remote access connections when the password management feature is enabled. You can also use MS-CHAPv2 with clientless connections.
- Authentication Proxy modes—Including RADIUS to Active Directory, RADIUS to RSA/SDI, RADIUS to Token-server, and RSA/SI to RADIUS connections,

**Note**

To enable MS-CHAPv2 as the protocol used between the adaptive security appliance and the RADIUS server for a VPN connection, password management must be enabled in the tunnel group general attributes. Enabling password management generates an MS-CHAPv2 authentication request from the adaptive security appliance to the RADIUS server. See the description of the **password-management** command for details.

If you use double authentication and enable password management in the tunnel group, then the primary and secondary authentication requests include MS-CHAPv2 request attributes. If a RADIUS server does not support MS-CHAPv2, then you can configure that server to send a non-MS-CHAPv2 authentication request by using the **no mschapv2-capable** command.

## Attribute Support

The adaptive security appliance supports the following sets of RADIUS attributes:

- Authentication attributes defined in RFC 2138.
- Accounting attributes defined in RFC 2139.
- RADIUS attributes for tunneled protocol support, defined in RFC 2868.
- Cisco IOS VSAs, identified by RADIUS vendor ID 9.
- Cisco VPN-related VSAs, identified by RADIUS vendor ID 3076.
- Microsoft VSAs, defined in RFC 2548.
- Cisco VSA (Cisco-Priv-Level), which provides a standard 0-15 numeric ranking of privileges, with 1 being the lowest level and 15 being the highest level. A zero level indicates no privileges. The first level (login) allows privileged EXEC access for the commands available at this level. The second level (enable) allows CLI configuration privileges.

## RADIUS Authorization Functions

The adaptive security appliance can use RADIUS servers for user authorization for network access using dynamic access lists or access list names per user. To implement dynamic access lists, you must configure the RADIUS server to support it. When the user authenticates, the RADIUS server sends a downloadable access list or access list name to the adaptive security appliance. Access to a given service is either permitted or denied by the access list. The adaptive security appliance deletes the access list when the authentication session expires.

## TACACS+ Server Support

The adaptive security appliance supports TACACS+ authentication with ASCII, PAP, CHAP, and MS-CHAPv1.

## RSA/SDI Server Support

The RSA SecureID servers are also known as SDI servers.

This section includes the following topics:

- [RSA/SDI Version Support, page 33-6](#)
- [Two-step Authentication Process, page 33-6](#)
- [RSA/SDI Primary and Replica Servers, page 33-6](#)

## RSA/SDI Version Support

The adaptive security appliance supports SDI Versions 5.0 and 6.0. SDI uses the concepts of an SDI primary and SDI replica servers. Each primary and its replicas share a single node secret file. The node secret file has its name based on the hexadecimal value of the ACE/Server IP address with .sdi appended.

A version 5.0 or 6.0 SDI server that you configure on the adaptive security appliance can be either the primary or any one of the replicas. See the [“RSA/SDI Primary and Replica Servers” section on page 33-6](#) for information about how the SDI agent selects servers to authenticate users.

## Two-step Authentication Process

SDI Versions 5.0 and 6.0 use a two-step process to prevent an intruder from capturing information from an RSA SecurID authentication request and using it to authenticate to another server. The agent first sends a lock request to the SecurID server before sending the user authentication request. The server locks the username, preventing another (replica) server from accepting it. This action means that the same user cannot authenticate to two adaptive security appliances using the same authentication servers simultaneously. After a successful username lock, the adaptive security appliance sends the passcode.

## RSA/SDI Primary and Replica Servers

The adaptive security appliance obtains the server list when the first user authenticates to the configured server, which can be either a primary or a replica. The adaptive security appliance then assigns priorities to each of the servers on the list, and subsequent server selection derives at random from those assigned priorities. The highest priority servers have a higher likelihood of being selected.

## NT Server Support

The adaptive security appliance supports Microsoft Windows server operating systems that support NTLM Version 1, collectively referred to as NT servers.

**Note**

---

NT servers have a maximum length of 14 characters for user passwords. Longer passwords are truncated, which is a limitation of NTLM Version 1.

---

## Kerberos Server Support

The adaptive security appliance supports 3DES, DES, and RC4 encryption types.

**Note**

---

The adaptive security appliance does not support changing user passwords during tunnel negotiation. To avoid this situation happening inadvertently, disable password expiration on the Kerberos/Active Directory server for users connecting to the adaptive security appliance.

---

For a simple Kerberos server configuration example, see [Example 33-2 on page 33-15](#).

## LDAP Server Support

The adaptive security appliance supports LDAP. For detailed information, see the [“Configuring an LDAP Server” section on page 33-15](#).

## HTTP Forms Authentication for Clientless SSL VPN

The adaptive security appliance can use the HTTP Form protocol for both authentication and single sign-on (SSO) operations of Clientless SSL VPN user sessions only.

## Local Database Support

The adaptive security appliance maintains a local database that you can populate with user profiles. This section includes the following topics:

- [User Profiles, page 33-7](#)
- [Fallback Support, page 33-7](#)

### User Profiles

User profiles include, at a minimum, a username. Typically, a password is assigned to each username, although passwords are optional.

To add other information to a specific user profile, enter the following command:

| Command                                                                                        | Purpose                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>username</b> {name} <b>attributes</b>                                                       | Enters username attributes mode, which lets you configure attributes for specific users. The information that you can add includes VPN-related attributes, such as a VPN session timeout value. |
| <b>Example:</b><br>hostname(config)# username anyuser attributes<br>hostname(config-username)# |                                                                                                                                                                                                 |

### Fallback Support

The local database can act as a fallback method for several functions. This behavior is designed to help you prevent accidental lockout from the adaptive security appliance.

For users who need fallback support, we recommend that their usernames and passwords in the local database match their usernames and passwords in the AAA servers. This practice provides transparent fallback support. Because the user cannot determine whether a AAA server or the local database is providing the service, using usernames and passwords on AAA servers that are different than the usernames and passwords in the local database means that the user cannot be certain which username and password should be given.

The local database supports the following fallback functions:

- **Console and enable password authentication**—When you use the **aaa authentication console** command, you can add the **LOCAL** keyword after the AAA server group tag. If the servers in the group are all unavailable, the adaptive security appliance uses the local database to authenticate administrative access, which can also include enable password authentication.

- Command authorization—When you use the **aaa authorization** command, you can add the **LOCAL** keyword after the AAA server group tag. If the TACACS+ servers in the group are all unavailable, the local database is used to authorize commands based on privilege levels.
- VPN authentication and authorization—VPN authentication and authorization are supported to enable remote access to the adaptive security appliance if AAA servers that normally support these VPN services are unavailable. The **authentication-server-group** command, available in tunnel-group general attributes mode, lets you specify the **LOCAL** keyword when you are configuring attributes of a tunnel group. When a VPN client of an administrator specifies a tunnel group configured to fallback to the local database, the VPN tunnel can be established even if the AAA server group is unavailable, provided that the local database is configured with the necessary attributes.

## Configuring the Local Database

This section describes how to manage users in the local database. You can use the local database for CLI access authentication, privileged mode authentication, command authorization, network access authentication, and VPN authentication and authorization. You cannot use the local database for network access authorization. The local database does not support accounting.

For multiple context mode, you can configure usernames in the system execution space to provide individual logins using the **login** command; however, you cannot configure any **aaa** commands in the system execution space.

To define a user account in the local database, perform the following steps:

|        | Command                                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p><b>username</b> <i>username</i> [<b>nopassword</b>   <b>password</b> <i>password</i> [<b>mschap</b>]] [<b>privilege</b> <i>priv_level</i>]</p> <p><b>Example:</b><br/> <pre>hostname(config)# username exampleuser1 privilege 1</pre></p> | <p>Creates the user account. The <i>username</i> keyword is a string from 4 to 64 characters long. The <b>password</b> <i>password</i> argument is a string from 3 to 16 characters long. The <b>mschap</b> keyword specifies that the password is converted to Unicode and hashed using MD4 after you enter it. Use this keyword if users are authenticated using MSCHAPv1 or MSCHAPv2. The <b>privilege level</b> argument sets the privilege level, which ranges from 0 to 15. The default is 2. This privilege level is used with command authorization.</p> <div>  <p><b>Caution</b> If you do not use command authorization (the <b>aaa authorization console LOCAL</b> command), then the default level 2 allows management access to privileged EXEC mode. If you want to limit access to privileged EXEC mode, either set the privilege level to 0 or 1, or use the <b>service-type</b> command (see <a href="#">Step 4</a>).</p> </div> <p>The <b>nopassword</b> keyword creates a user account with no password.</p> <p>The <b>encrypted</b> and <b>nt-encrypted</b> keywords are typically for display only. When you define a password in the <b>username</b> command, the adaptive security appliance encrypts it when it saves it to the configuration for security purposes. When you enter the <b>show running-config</b> command, the <b>username</b> command does not show the actual password; it shows the encrypted password followed by the <b>encrypted</b> or <b>nt-encrypted</b> keyword (when you specify <b>mschap</b>). For example, if you enter the password “test,” the <b>show running-config</b> output would appear as something similar to the following:</p> <pre>username user1 password DLaUiAX3l78qgoB5c7iVNw== nt-encrypted</pre> <p>The only time you would actually enter the <b>encrypted</b> or <b>nt-encrypted</b> keyword at the CLI is if you are cutting and pasting a configuration file for use in another adaptive security appliance, and you are using the same password.</p> |

|        | Command                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 2 | <b>aaa authorization exec authentication-server</b><br><br><b>Example:</b><br><pre>hostname(config)# aaa authorization exec authentication-server</pre> | <p>(Optional) Enforces user-specific access levels for users who authenticate for management access (see the <b>aaa authentication console LOCAL</b> command). This command enables management authorization for local users and for any users authenticated by RADIUS, LDAP, and TACACS+. See the <a href="#">“Limiting User CLI and ASDM Access with Management Authorization”</a> section on page 34-13 for information about configuring a user on a AAA server to accommodate management authorization.</p> <p>For a local user, configure the level of access using the <b>service-type</b> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 3 | <b>username username attributes</b><br><br><b>Example:</b><br><pre>hostname(config)# username exampleuser1 attributes</pre>                             | <p>(Optional) Configures username attributes. The <i>username</i> argument is the username that you created in <a href="#">Step 1</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 4 | <b>service-type {admin   nas-prompt   remote-access}</b><br><br><b>Example:</b><br><pre>hostname(config-username)# service-type admin</pre>             | <p>(Optional) Configures the user level if you configured management authorization in Step 2. The <b>admin</b> keyword allows full access to any services specified by the <b>aaa authentication console LOCAL</b> commands. The <b>admin</b> keyword is the default.</p> <p>The <b>nas-prompt</b> keyword allows access to the CLI when you configure the <b>aaa authentication {telnet   ssh   serial} console LOCAL</b> command, but denies ASDM configuration access if you configure the <b>aaa authentication http console LOCAL</b> command. ASDM monitoring access is allowed. If you enable authentication with the <b>aaa authentication enable console LOCAL</b> command, the user cannot access privileged EXEC mode using the <b>enable</b> command (or the <b>login</b> command).</p> <p>The <b>remote-access</b> keyword denies management access. The user cannot use any services specified by the <b>aaa authentication console LOCAL</b> commands (excluding the <b>serial</b> keyword; serial access is allowed).</p> <p>(Optional) If you are using this username for VPN authentication, you can configure many VPN attributes for the user. For more information, see the <a href="#">“Configuring Attributes for Specific Users”</a> section on page 63-82.</p> |

## Examples

The following command assigns a privilege level of 15 to the admin user account:

```
hostname(config)# username admin password passw0rd privilege 15
```

The following command creates a user account with no password:

```
hostname(config)# username user34 nopassword
```

The following commands enable management authorization, create a user account with a password, enter username attributes configuration mode, and specify the service-type attribute:

```
hostname(config)# aaa authorization exec authentication-server  
hostname(config)# username user1 password g0ge0us  
hostname(config)# username user1 attributes  
hostname(config-username)# service-type nas-prompt
```

## Identifying AAA Server Groups and Servers

If you want to use an external AAA server for authentication, authorization, or accounting, you must first create at least one AAA server group per AAA protocol and add one or more servers to each group. You identify AAA server groups by name. Each server group is specific to one type of server: Kerberos, LDAP, NT, RADIUS, SDI, or TACACS+.

You can have up to 100 server groups in single mode or 4 server groups per context in multiple mode. Each group can have up to 16 servers in single mode or 4 servers in multiple mode. When a user logs in, the servers are accessed one at a time starting with the first server you specify in the configuration, until a server responds. If all servers in the group are unavailable, the adaptive security appliance tries the local database if you configured it as a fallback method (management authentication and authorization only). If you do not have a fallback method, the adaptive security appliance continues to try the AAA servers.

## How Fallback Works with Multiple Servers in a Group

If you configure multiple servers in a server group and you enable fallback to the local database for the server group, fallback occurs when no server in the group responds to the authentication request from the adaptive security appliance. To illustrate, consider this scenario:

You configure an LDAP server group with two Active Directory servers, server 1 and server 2, in that order. When the remote user logs in, the adaptive security appliance attempts to authenticate to server 1.

If server 1 responds with an authentication failure (such as *user not found*), the adaptive security appliance does not attempt to authenticate to server 2.

If server 1 does not respond within the timeout period (or the number of authentication attempts exceeds the configured maximum), the adaptive security appliance tries server 2.

If both servers in the group do not respond, and the adaptive security appliance is configured to fallback to the local database, the adaptive security appliance attempts to authenticate to the local database.

To create a server group and add AAA servers to it, perform the following steps:

|        | Command                                                                                                                                                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>aaa-server</b> <i>server_group</i> <b>protocol</b> { <b>kerberos</b>   <b>ldap</b>   <b>nt</b>   <b>radius</b>   <b>sdi</b>   <b>tacacs+</b> }<br><br><b>Example:</b><br><pre>hostname(config)# aaa-server servergroup1 protocol ldap hostname(config-aaa-server-group)#</pre> | <p>Identifies the server group name and the protocol. For example, to use RADIUS to authenticate network access and TACACS+ to authenticate CLI access, you need to create at least two server groups, one for RADIUS servers and one for TACACS+ servers.</p> <p>You can have up to 15 single-mode server groups or 4 multi-mode server groups. Each server group can have up to 16 servers in single mode or up to 4 servers in multi-mode.</p> <p>When you enter the <b>aaa-server protocol</b> command, you enter <b>aaa-server group</b> mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 2 | <b>max-failed-attempts</b> <i>number</i><br><br><b>Example:</b><br><pre>hostname(config-aaa-server-group)# max-failed-attempts 2</pre>                                                                                                                                            | <p>Specifies the maximum number of requests sent to a AAA server in the group before trying the next server. The <i>number</i> argument can range from 1 and 5. The default is 3.</p> <p>If you configured a fallback method using the local database (for management access only; see the <a href="#">“Configuring Local Command Authorization”</a> section on page 34-16 and the <a href="#">“Configuring TACACS+ Command Authorization”</a> section on page 34-21 to configure the fallback mechanism), and all the servers in the group fail to respond, then the group is considered to be unresponsive, and the fallback method is tried. The server group remains marked as unresponsive for a period of 10 minutes (by default) so that additional AAA requests within that period do not attempt to contact the server group, and the fallback method is used immediately. To change the unresponsive period from the default, see the <b>reactivation-mode</b> command in the next step.</p> <p>If you do not have a fallback method, the adaptive security appliance continues to retry the servers in the group.</p> |
| Step 3 | <b>reactivation-mode</b> { <b>depletion</b> [ <b>deadtime</b> <i>minutes</i> ]   <b>timed</b> }<br><br><b>Example:</b><br><pre>hostname(config-aaa-server-group)# reactivation-mode deadtime 20</pre>                                                                             | <p>Specifies the method (reactivation policy) by which failed servers in a group are reactivated.</p> <p>The <b>depletion</b> keyword reactivates failed servers only after all of the servers in the group are inactive.</p> <p>The <b>deadtime</b> <i>minutes</i> argument specifies the amount of time in minutes, between 0 and 1440, that elapses between the disabling of the last server in the group and the subsequent reenabling of all servers. The default is 10 minutes.</p> <p>The <b>timed</b> keyword reactivates failed servers after 30 seconds of down time.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|               | Command                                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 4</b> | <b>accounting-mode simultaneous</b><br><br><b>Example:</b><br><pre>hostname(config-aaa-server-group)# accounting-mode simultaneous</pre>                                                              | <p>Sends accounting messages to all servers in the group (RADIUS or TACACS+ only).</p> <p>To restore the default of sending messages only to the active server, enter the <b>accounting-mode single</b> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 5</b> | <b>aaa-server server_group (interface_name) host server_ip</b><br><br><b>Example:</b><br><pre>hostname(config)# aaa-server servergroup1 outside host 10.10.1.1 hostname(config-aaa-server-host)</pre> | <p>Identifies the server and the AAA server group to which it belongs.</p> <p>When you enter the <b>aaa-server host</b> command, you enter <b>aaa-server host</b> mode. As needed, use host mode commands to further configure the AAA server.</p> <p>The commands in host mode do not apply to all AAA server types. <a href="#">Table 33-2</a> lists the available commands, the server types to which they apply, and whether a new AAA server definition has a default value for that command. Where a command is applicable to the specified server type and no default value is provided (indicated by “—”), use the command to specify the value.</p> |

**Table 33-2 Host Mode Commands, Server Types, and Defaults**

| Command                          | Applicable AAA Server Types | Default Value |
|----------------------------------|-----------------------------|---------------|
| <b>accounting-port</b>           | RADIUS                      | 1646          |
| <b>acl-netmask-convert</b>       | RADIUS                      | standard      |
| <b>authentication-port</b>       | RADIUS                      | 1645          |
| <b>kerberos-realm</b>            | Kerberos                    | —             |
| <b>key</b>                       | RADIUS                      | —             |
|                                  | TACACS+                     | —             |
| <b>ldap-attribute-map</b>        | LDAP                        | —             |
| <b>ldap-base-dn</b>              | LDAP                        | —             |
| <b>ldap-login-dn</b>             | LDAP                        | —             |
| <b>ldap-login-password</b>       | LDAP                        | —             |
| <b>ldap-naming-attribute</b>     | LDAP                        | —             |
| <b>ldap-over-ssl</b>             | LDAP                        | —             |
| <b>ldap-scope</b>                | LDAP                        | —             |
| <b>maschapv2-capable</b>         | RADIUS                      | enabled       |
| <b>nt-auth-domain-controller</b> | NT                          | —             |
| <b>radius-common-pw</b>          | RADIUS                      | —             |
| <b>retry-interval</b>            | Kerberos                    | 10 seconds    |
|                                  | RADIUS                      | 10 seconds    |
|                                  | SDI                         | 10 seconds    |

**Table 33-2** Host Mode Commands, Server Types, and Defaults (continued)

| Command               | Applicable AAA Server Types | Default Value  |
|-----------------------|-----------------------------|----------------|
| <b>sasl-mechanism</b> | LDAP                        | —              |
| <b>server-port</b>    | Kerberos                    | 88             |
|                       | LDAP                        | 389            |
|                       | NT                          | 139            |
|                       | SDI                         | 5500           |
|                       | TACACS+                     | 49             |
| <b>server-type</b>    | LDAP                        | auto-discovery |
| <b>timeout</b>        | All                         | 10 seconds     |

## Examples

[Example 33-1](#) shows commands that add one TACACS+ group with one primary and one backup server, one RADIUS group with a single server, and an NT domain server.

### Example 33-1 Multiple AAA Server Groups and Servers

```
hostname(config)# aaa-server AuthInbound protocol tacacs+
hostname(config-aaa-server-group)# max-failed-attempts 2
hostname(config-aaa-server-group)# reactivation-mode depletion deadtime 20
hostname(config-aaa-server-group)# exit
hostname(config)# aaa-server AuthInbound (inside) host 10.1.1.1
hostname(config-aaa-server-host)# key TACPlusUauthKey
hostname(config-aaa-server-host)# exit
hostname(config)# aaa-server AuthInbound (inside) host 10.1.1.2
hostname(config-aaa-server-host)# key TACPlusUauthKey2
hostname(config-aaa-server-host)# exit
hostname(config)# aaa-server AuthOutbound protocol radius
hostname(config-aaa-server-group)# exit
hostname(config)# aaa-server AuthOutbound (inside) host 10.1.1.3
hostname(config-aaa-server-host)# key RadUauthKey
hostname(config-aaa-server-host)# exit
hostname(config)# aaa-server NTAAuth protocol nt
hostname(config-aaa-server-group)# exit
hostname(config)# aaa-server NTAAuth (inside) host 10.1.1.4
hostname(config-aaa-server-host)# nt-auth-domain-controller primary1
hostname(config-aaa-server-host)# exit
```

[Example 33-2](#) shows commands that configure a Kerberos AAA server group named watchdogs, add a AAA server to the group, and define the Kerberos realm for the server. Because [Example 33-2](#) does not define a retry interval or the port that the Kerberos server listens to, the adaptive security appliance uses the default values for these two server-specific parameters. [Table 33-2](#) lists the default values for all AAA server host mode commands.

#### Note

Kerberos realm names use numbers and upper-case letters only. Although the adaptive security appliance accepts lower-case letters for a realm name, it does not translate lower-case letters to upper-case letters. Be sure to use upper-case letters only.

**Example 33-2 Kerberos Server Group and Server**

```
hostname(config)# aaa-server watchdogs protocol kerberos
hostname(config-aaa-server-group)# aaa-server watchdogs host 192.168.3.4
hostname(config-aaa-server-host)# kerberos-realm EXAMPLE.COM
hostname(config-aaa-server-host)# exit
hostname(config)#
```

## Configuring an LDAP Server

This section describes how to configure an LDAP directory with the adaptive security appliance for user authentication and VPN authorization and includes the following topics:

- [Authentication with LDAP, page 33-15](#)
- [Authorization with LDAP for VPN, page 33-17](#)
- [LDAP Attribute Mapping for Authorization, page 33-18](#)

## Authentication with LDAP

During authentication, the adaptive security appliance acts as a client proxy to the LDAP server for the user, and authenticates to the LDAP server in either plain text or by using the SASL protocol. By default, the adaptive security appliance passes authentication parameters, usually a username and password, to the LDAP server in plain text. Whether using SASL or plain text, you can secure communications between the adaptive security appliance and the LDAP server with SSL using the **ldap-over-ssl** command.

**Note**

If you do not configure SASL, we strongly recommend that you secure LDAP communications with SSL using the **ldap-over-ssl** command.

When user LDAP authentication has succeeded, the LDAP server returns the attributes for the authenticated user. For VPN authentication, these attributes generally include authorization data that is applied to the VPN session. Thus, using LDAP accomplishes authentication and authorization in a single step.

## Securing LDAP Authentication with SASL

The adaptive security appliance supports the following SASL mechanisms, listed in order of increasing strength:

- Digest-MD5—The adaptive security appliance responds to the LDAP server with an MD5 value computed from the username and password.
- Kerberos—The adaptive security appliance responds to the LDAP server by sending the username and realm using the GSSAPI Kerberos mechanism.

You can configure the adaptive security appliance and LDAP server to support any combination of these SASL mechanisms. If you configure multiple mechanisms, the adaptive security appliance retrieves the list of SASL mechanisms that are configured on the server and sets the authentication mechanism to the strongest mechanism configured on both the adaptive security appliance and the server. For example, if both the LDAP server and the adaptive security appliance support both mechanisms, the adaptive security appliance selects Kerberos, the stronger of the mechanisms.

## Examples

The following example configures the adaptive security appliance for authentication to an LDAP directory server named `ldap_dir_1` using the digest-MD5 SASL mechanism, and communicating over an SSL-secured connection:

```
hostname(config)# aaa-server ldap_dir_1 protocol ldap
hostname(config-aaa-server-group)# aaa-server ldap_dir_1 host 10.1.1.4
hostname(config-aaa-server-host)# sasl-mechanism digest-md5
hostname(config-aaa-server-host)# ldap-over-ssl enable
hostname(config-aaa-server-host)#
```

## Setting the LDAP Server Type

The adaptive security appliance supports LDAP version 3 and is compatible with the Sun Microsystems JAVA System Directory Server (formerly named the Sun ONE Directory Server), the Microsoft Active Directory, Novell, OpenLDAP, and other LDAPv3 directory servers.

By default, the adaptive security appliance auto-detects whether it is connected to Microsoft Active Directory, Sun LDAP, Novell, OpenLDAP, or a generic LDAPv3 directory server. However, if auto-detection fails to determine the LDAP server type, and you know the server is either a Microsoft, Sun or generic LDAP server, you can manually configure the server type using the keywords **sun**, **microsoft**, **novell**, **openldap**, or **generic**.

## Examples

The following example sets the LDAP directory server “`ldap_dir_1`” to the Sun Microsystems type:

```
hostname(config)# aaa-server ldap_dir_1 protocol ldap
hostname(config-aaa-server-group)# aaa-server ldap_dir_1 host 10.1.1.4
hostname(config-aaa-server-host)# server-type sun
hostname(config-aaa-server-host)#
```

### Note

- The DN configured on the adaptive security appliance to access a Sun directory server must be able to access the default password policy on that server. We recommend using the directory administrator, or a user with directory administrator privileges, as the DN. Alternatively, you can place an ACI on the default password policy.
- You must configure LDAP over SSL to enable password management with Microsoft Active Directory and Sun servers.
- The adaptive security appliance does not support password management with Novell, OpenLDAP, and other LDAPv3 directory servers.
- The adaptive security appliance uses the Login Distinguished Name (DN) and Login Password to establish trust (bind) with an LDAP server. The Login DN represents a user record in the LDAP server that the administrator uses for binding. When binding, the adaptive security appliance authenticates to the server using the Login DN and the Login password. For example, when performing a Microsoft Active Directory read-only operation (such as authentication, authorization, or group-search), the adaptive security appliance can bind with a Login DN with fewer privileges. For example, the Login DN can be a user whose AD “Member Of” designation is part of Domain Users. For VPN password management operations, the Login DN needs elevated privileges and must be part of the Account Operators AD group. The following is an example of a Login DN:  
`cn=Binduser1,ou=Admins,ou=Users,dc=company_A,dc=com`
- The adaptive security appliance supports the following authentication methods:

- Simple LDAP authentication with an unencrypted password on port 389
- Secure LDAP (LDAP-S) on port 636
- Simple Authentication and Security Layer (SASL) MD5
- SASL Kerberos

**Note** The adaptive security appliance does not support anonymous authentication.

## Authorization with LDAP for VPN

When user LDAP authentication for VPN access has succeeded, the adaptive security appliance queries the LDAP server which returns LDAP attributes. These attributes generally include authorization data that applies to the VPN session. Thus, using LDAP accomplishes authentication and authorization in a single step.

There may be cases, however, where you require authorization from an LDAP directory server that is separate and distinct from the authentication mechanism. For example, if you use an SDI or certificate server for authentication, no authorization information is passed back. For user authorizations in this case, you can query an LDAP directory after successful authentication, accomplishing authentication and authorization in two steps.

To set up VPN user authorization using LDAP, perform the following steps:

|               | Command                                                                                                                                                                                                                                                                        | Purpose                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>aaa-server</b> <i>server_group</i> <b>protocol</b> { <b>kerberos</b>   <b>ldap</b>   <b>nt</b><br>  <b>radius</b>   <b>sdi</b>   <b>tacacs+</b> }<br><br><b>Example:</b><br>hostname(config)# aaa-server servergroup1 protocol<br>ldap<br>hostname(config-aaa-server-group) | Creates a AAA server group.                                                            |
| <b>Step 2</b> | <b>tunnel-group</b> <i>groupname</i><br><br><b>Example:</b><br>hostname(config)# tunnel-group remotegrp                                                                                                                                                                        | Creates an IPSec remote access tunnel group named “remotegrp.”                         |
| <b>Step 3</b> | <b>tunnel-group</b> <i>groupname</i> <b>general-attributes</b><br><br><b>Example:</b><br>hostname(config)# tunnel-group remotegrp<br>general-attributes                                                                                                                        | Associates the server group and the tunnel group.                                      |
| <b>Step 4</b> | <b>authorization-server-group</b> <i>group-tag</i><br><br><b>Example:</b><br>hostname(config-general)# <b>authorization-server-group</b><br>ldap_dir_1                                                                                                                         | Assigns a new tunnel group to a previously created AAA server group for authorization. |

### Examples

While there are other authorization-related commands and options available for specific requirements, the following example shows fundamental commands for enabling user authorization with LDAP. The example then creates an IPsec remote access tunnel group named “remote-1,” and assigns that new tunnel group to the previously created “ldap\_dir\_1” AAA server group for authorization:

```
hostname(config)# tunnel-group remote-1 type ipsec-ra
hostname(config)# tunnel-group remote-1 general-attributes
hostname(config-general)# authorization-server-group ldap_dir_1
hostname(config-general)#
```

After you complete this fundamental configuration work, you can then configure additional LDAP authorization parameters such as a directory password, a starting point for searching a directory, and the scope of a directory search by entering the following commands:

```
hostname(config)# aaa-server ldap_dir_1 protocol ldap
hostname(config-aaa-server-group)# aaa-server ldap_dir_1 host 10.1.1.4
hostname(config-aaa-server-host)# ldap-login-dn obscurepassword
hostname(config-aaa-server-host)# ldap-base-dn starthere
hostname(config-aaa-server-host)# ldap-scope subtree
hostname(config-aaa-server-host)#
```

## LDAP Attribute Mapping for Authorization

If you are introducing an adaptive security appliance to an existing LDAP directory, your existing LDAP attribute names and values are probably different from the current ones. You must create LDAP attribute maps that map your existing user-defined attribute names and values to Cisco attribute names and values that are compatible with the adaptive security appliance. You can then bind these attribute maps to LDAP servers or remove them, as needed. You can also show or clear attribute maps.

**Note**

For more information about LDAP attribute maps, see [Active Directory/LDAP VPN Remote Access Authorization Use Cases](#), page C-16.

To create an unpopulated LDAP attribute map table, enter the following command:

| Command                                                                                                  | Purpose                                                            |
|----------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| <b>ldap attribute-map</b> <i>map-name</i>                                                                | Creates an unpopulated LDAP attribute map table named “att_map_1.” |
| <b>Example:</b><br>hostname(config)# ldap attribute-map att_map_1<br>hostname(config-ldap-attribute-map) |                                                                    |

To map a user-defined attribute name to the Cisco attribute name, enter the following command:

| Command                                                                                          | Purpose                                                                                            |
|--------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <b>map-name</b> <i>user-attribute-name Cisco-attribute-name</i>                                  | Maps the user-defined attribute name “department” to the Cisco attribute name “IETF-Radius-Class.” |
| <b>Example:</b><br>hostname(config-ldap-attribute-map)# map-name<br>department IETF-Radius-Class |                                                                                                    |

To map a user-defined map value to the user-defined attribute value and the Cisco-defined attribute value, enter the following command:

| Command                                                                                                                                        | Purpose                                                                                                                                |
|------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>map-value</b> <i>user-attribute-name</i> <i>Cisco-attribute-name</i>                                                                        | Maps the user-defined map value “department” to the user defined attribute value “Engineering” and the Cisco attribute value “group1.” |
| <b>Example:</b><br><pre>hostname(config-ldap-attribute-map)# map-value department Engineering group1 hostname(config-ldap-attribute-map)</pre> |                                                                                                                                        |

To bind the attribute map to the LDAP server, enter the following commands:

|               | Command                                                                                                                                                                                    | Purpose                                                                                                                                                                               |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>aaa-server</b> <i>server_group</i> ( <i>interface_name</i> )<br><b>host</b> <i>server_ip</i><br><br><b>Example:</b><br><pre>hostname(config)# aaa-server ldap_dir_1 host 10.1.1.4</pre> | Identifies the server and the AAA server group to which it belongs. Creates the LDAP server group “ldap_dir_1” and identifies the host IP address “10.1.1.4” to which it is assigned. |
| <b>Step 2</b> | <b>ldap-attribute-map</b> <i>map-name</i><br><br><b>Example:</b><br><pre>hostname(config-aaa-server-host)# ldap-attribute-map att_map_1 hostname(config-aaa-server-host)</pre>             | Binds the attribute map “att_map_1” to the LDAP server “ldap_dir_1.”                                                                                                                  |

#### Note

The command to create an attribute map (**ldap attribute-map**) and the command to bind it to an LDAP server (**ldap-attribute-map**) differ only by a hyphen and the mode.

The names of frequently mapped Cisco LDAP attributes and the type of user-defined attributes they would commonly be mapped to include the following:

- IETF-Radius-Class—A department or user group
- IETF-Radius-Filter-Id—An access control list enforced on IPsec and SSL VPN clients
- IETF-Radius-Framed-IP-Address—A static IP address
- Banner1—A message displayed to VPN users at login
- Tunneling-Protocols—Allows or denies dial-in

### Examples

The following example shows how to limit management sessions to the adaptive security appliance based on an LDAP attribute called accessType. The accessType attribute has three possible values:

- VPN
- admin
- helpdesk

Each value is mapped to one of the valid IETF RADIUS Service-Types that the adaptive security appliance supports: remote-access (Service-Type 5) Outbound, admin (Service-Type 6) Administrative, and nas-prompt (Service-Type 7) NAS Prompt:

```
hostname(config)# ldap attribute-map MGMT
hostname(config-ldap-attribute-map)# map-name accessType IETF-Radius-Service-Type
hostname(config-ldap-attribute-map)# map-value accessType VPN 5
hostname(config-ldap-attribute-map)# map-value accessType admin 6
hostname(config-ldap-attribute-map)# map-value accessType helpdesk 7

hostname(config-ldap-attribute-map)# aaa-server LDAP protocol ldap
hostname(config-aaa-server-group)# aaa-server LDAP (inside) host 10.1.254.91
hostname(config-aaa-server-host)# ldap-base-dn CN=Users,DC=cisco,DC=local
hostname(config-aaa-server-host)# ldap-scope subtree
hostname(config-aaa-server-host)# ldap-login-password test
hostname(config-aaa-server-host)# ldap-login-dn
CN=Administrator,CN=Users,DC=cisco,DC=local
hostname(config-aaa-server-host)# server-type auto-detect
hostname(config-aaa-server-host)# ldap-attribute-map MGMT
```

The following example shows how to display the complete list of Cisco LDAP attribute names:

```
hostname(config)# ldap attribute-map att_map_1
hostname(config-ldap-attribute-map)# map-name att_map_1?

ldap mode commands/options:

  Access-Hours
  Allow-Network-Extension-Mode
  Auth-Service-Type
  Authenticated-User-Idle-Timeout
  Authorization-Required
  Authorization-Type
  :
  :
  X509-Cert-Data
hostname(config-ldap-attribute-map)#
```

## Using Certificates and User Login Credentials

The following section describes the different methods of using certificates and user login credentials (username and password) for authentication and authorization. These methods apply to both IPsec and Clientless SSL VPN.

In all cases, LDAP authorization does not use the password as a credential. RADIUS authorization uses either a common password for all users or the username as a password.

This section includes the following topics:

- [Using User Login Credentials, page 33-20](#)
- [Using Certificates, page 33-21](#)

## Using User Login Credentials

The default method for authentication and authorization uses the user login credentials.

- Authentication
  - Enabled by authentication server group setting

- Uses the username and password as credentials
- Authorization
  - Enabled by authorization server group setting
  - Uses the username as a credential

## Using Certificates

If user digital certificates are configured, the adaptive security appliance first validates the certificate. It does not, however, use any of the DNs from certificates as a username for the authentication.

If both authentication and authorization are enabled, the adaptive security appliance uses the user login credentials for both user authentication and authorization.

- Authentication
  - Enabled by authentication server group setting
  - Uses the username and password as credentials
- Authorization
  - Enabled by authorization server group setting
  - Uses the username as a credential

If authentication is disabled and authorization is enabled, the adaptive security appliance uses the primary DN field for authorization.

- Authentication
  - DISABLED (set to None) by the authentication server group setting
  - No credentials used
- Authorization
  - Enabled by authorization server group setting
  - Uses the username value of the certificate primary DN field as a credential

### Note

If the primary DN field is not present in the certificate, the adaptive security appliance uses the secondary DN field value as the username for the authorization request.

For example, consider a user certificate that includes the following Subject DN fields and values:

**Cn=anyuser,OU=sales,O=XYZCorporation,L=boston,S=mass,C=us,ea=anyuser@example.com**

If the Primary DN = EA (E-mail Address) and the Secondary DN = CN (Common Name), then the username used in the authorization request would be anyuser@example.com.

## Differentiating User Roles Using AAA

This section includes the following topics:

- [Using Local Authentication, page 33-22](#)
- [Using RADIUS Authentication, page 33-22](#)
- [Using LDAP Authentication, page 33-23](#)

- [Using TACACS+ Authentication, page 33-23](#)

The adaptive security appliance enables you to distinguish between administrative and remote-access users when they authenticate using RADIUS, LDAP, TACACS+, or the local user database. User role differentiation can prevent remote access VPN and network access users from establishing an administrative connection to the adaptive security appliance.

To differentiate user roles, use the **service-type** attribute in username configuration mode. For RADIUS and LDAP (with the **ldap-attribute-map** command), you can use a Cisco Vendor-Specific Attribute (VSA), Cisco-Priv-Level, to assign a privilege level to an authenticated user.

## Using Local Authentication

Before you configure the **service-type** attribute and privilege level when using local authentication, you must create a user, assign a password, and assign a privilege level. To do so, enter the following command:

```
hostname(config)# username admin password mysecret123 privilege 15
```

Where **mysecret123** is the stored password and 15 is the assigned privilege level, which indicates an admin user.

The available configuration options for the **service-type** attribute include the following:

- **admin**, in which users are allowed access to the configuration mode. This option also allows a user to connect via remote access.
- **nas-prompt**, in which users are allowed access to the EXEC mode.
- **remote-access**, in which users are allowed access to the network.

The following example designates a **service-type** of **admin** for a user named admin:

```
hostname(config)# username admin attributes
hostname(config-username)# service-type admin
```

The following example designates a **service-type** of **remote-access** for a user named ra-user:

```
hostname(config)# username ra-user attributes
hostname(config-username)# service-type remote-access
```

## Using RADIUS Authentication

The RADIUS IETF **service-type** attribute, when sent in an access-accept message as the result of a RADIUS authentication and authorization request, is used to designate which type of service is granted to the authenticated user. The supported attribute values are the following: administrative(6), nas-prompt(7), Framed(2), and Login(1).

For more information about using RADIUS authentication, see the [“Configuring an External RADIUS Server” section on page C-30](#). For more information about configuring RADIUS authentication for Cisco Secure ACS, see the Cisco Secure ACS documentation on Cisco.com.

The RADIUS Cisco VSA **privilege-level** attribute (Vendor ID 3076, sub-ID 220), when sent in an access-accept message, is used to designate the level of privilege for the user. For a list of supported RADIUS VSAs used for authorization, see the [“Configuring an External RADIUS Server” section on page C-30](#).

## Using LDAP Authentication

When users are authenticated through LDAP, the native LDAP attributes and their values can be mapped to Cisco adaptive security appliance attributes to provide specific authorization features. For the supported list of LDAP VSAs used for authorization, see the [“Configuring an External LDAP Server” section on page C-3](#).

You can use the LDAP attribute mapping feature for LDAP authorization. For examples of this feature, see the [“Understanding Policy Enforcement of Permissions and Attributes” section on page C-2](#).

The following example shows how to define an LDAP attribute map. In this example, the security policy specifies that users being authenticated through LDAP map the user record fields or parameters title and company to the IETF-RADIUS service-type and privilege-level, respectively.

To define an LDAP attribute map, enter the following commands:

```
hostname(config)# ldap attribute-map admin-control
hostname(config-ldap-attribute-map)# map-name title IETF-RADIUS-Service-Type
hostname(config-ldap-attribute-map)# map-name company Privilege-Level
```

The following is sample output from the **ldap-attribute-map** command:

```
ldap attribute-map admin-control
  map-name company Privilege-Level
  map-name title IETF-Radius-Service-Type
```

To apply the LDAP attribute map to the LDAP AAA server, enter the following commands:

```
hostname(config)# aaa-server ldap-server (dmz1) host 10.20.30.1
hostname(config-aaa-server-host)# ldap-attribute-map admin-control
```

### Note

When an authenticated user tries administrative access to the adaptive security appliance through ASDM, SSH, or Telnet, but does not have the appropriate privilege level to do so, the adaptive security appliance generates syslog message 113021. This message informs the user that the attempted login failed because of inappropriate administrative privileges.

## Using TACACS+ Authentication

For information about how to configure TACACS+ authentication, see the [“Configuring an External TACACS+ Server” section on page C-39](#).

## AAA Servers Monitoring Commands

To monitor AAA Servers, enter one of the following commands:

| Command                      | Purpose                                                                                      |
|------------------------------|----------------------------------------------------------------------------------------------|
| <code>show aaa-server</code> | Shows the configured AAA server statistics.                                                  |
|                              | To clear the aaa server configuration, enter the <b>clear aaa-server statistics</b> command. |

|                                                         |                                                                                                                                                                                              |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>show running-config aaa-server</code>             | Shows the AAA server running configuration.<br>To clear aaa server statistics, enter the <b>clear configure aaa-server</b> command.                                                          |
| <code>show running-config all ldap attribute-map</code> | Shows all LDAP attribute maps in the running configuration.<br>To clear all LDAP attribute maps in the running configuration, use the <b>clear configuration ldap attribute-map</b> command. |
| <code>show running-config zonelabs-integrity</code>     | Shows the Zone Labs Integrity server configuration.<br>To clear the Zone Labs Integrity server configuration, use the <b>clear configure zonelabs-integrity</b> command.                     |
| <code>show ad-groups name [filter string]</code>        | Applies only to AD servers using LDAP, and shows groups that are listed on an AD server.                                                                                                     |

# CHAPTER 34

## Configuring Management Access

---

This chapter describes how to access the adaptive security appliance for system management through Telnet, SSH, and HTTPS (using ASDM). It also describes how to authenticate and authorize users and how to create login banners.

This chapter includes the following sections:

- [Configuring Device Access for ASDM, Telnet, or SSH, page 34-1](#)
- [Configuring CLI Parameters, page 34-6](#)
- [Configuring ICMP Access, page 34-8](#)
- [Configuring Management Access Over a VPN Tunnel, page 34-10](#)
- [Configuring AAA for System Administrators, page 34-10](#)

### Note

To access the adaptive security appliance interface for management access, you do not also need an access list allowing the host IP address. You only need to configure management access according to the sections in this chapter.

To configure the management IP address for transparent firewall mode, see the [“Setting the Management IP Address for a Transparent Firewall”](#) section on page 7-12.

---

## Configuring Device Access for ASDM, Telnet, or SSH

This section describes how to allow clients to access the device using ASDM, Telnet, or SSH, and includes the following topics:

- [Configuring Telnet Access, page 34-2](#)
- [Configuring SSH Access, page 34-3](#)
- [Using an SSH Client, page 34-4](#)
- [Configuring HTTPS Access for ASDM, page 34-5](#)

# Configuring Telnet Access

The adaptive security appliance allows Telnet connections to the adaptive security appliance for management purposes. To gain access to the adaptive security appliance console using Telnet, enter the username **asa** and the login password set by the **password** command or log in by using the **aaa authentication telnet console** command.

## Restrictions

You cannot use Telnet to the lowest security interface unless you use Telnet inside an IPsec tunnel.

The adaptive security appliance allows a maximum of 5 concurrent Telnet connections per context, if available, with a maximum of 100 connections divided between all contexts.

Management access to an interface other than the one from which you entered the adaptive security appliance is not supported. For example, if your management host is located on the outside interface, you can only initiate a management connection directly to the outside interface. The only exception to this rule is through a VPN connection, and entering the **management-access** command. For more information about the **management-access** command, see the *Cisco ASA 5500 Series Command Reference*.

## Detailed Steps

To configure Telnet access, perform the following steps:

|        | Command                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>telnet</b> <i>source_IP_address mask source_interface</i><br><br><b>Example:</b><br>hostname(config)# <b>telnet</b> 192.168.1.2 255.255.255.255 inside | Identifies the IP addresses from which the adaptive security appliance accepts connections. Make sure that you perform this step for each address or subnet.<br><br>If there is only one interface, you can configure Telnet to access that interface as long as the interface has a security level of 100.                                                       |
| Step 2 | <b>telnet timeout</b> <i>minutes</i><br><br><b>Example:</b><br>hostname(config)# <b>telnet timeout</b> 30                                                 | (Optional) Sets the duration for how long a Telnet session can be idle before the adaptive security appliance disconnects the session.<br><br>Set the timeout from 1 to 1440 minutes. The default is 5 minutes. The default duration is too short in most cases, and should be increased until all pre-production testing and troubleshooting has been completed. |

## Examples

The following example allows a host on the inside interface with an address of 192.168.1.2 to access the adaptive security appliance:

```
hostname(config)# telnet 192.168.1.2 255.255.255.255 inside
hostname(config)# telnet timeout 30
```

The following example allows all users on the 192.168.3.0 network to access the adaptive security appliance on the inside interface:

```
hostname(config)# telnet 192.168.3.0 255.255.255.0 inside
```

## Configuring SSH Access

The adaptive security appliance allows SSH connections to the adaptive security appliance for management purposes. To gain access to the adaptive security appliance console using SSH, at the SSH client prompt, enter the username **asa** and the login password set by the **password** command or log in by using the **aaa authentication telnet console** command.

### Restrictions

The adaptive security appliance allows a maximum of 5 concurrent SSH connections per context, if available, with a maximum of 100 connections divided between all contexts.

SSH is an application running on top of a reliable transport layer, such as TCP/IP, that provides strong authentication and encryption capabilities. The adaptive security appliance supports the SSH remote shell functionality provided in SSH Versions 1 and 2 and supports DES and 3DES ciphers.

#### Note

XML management over SSL and SSH are not supported.

In addition, management access to an interface other than the one from which you entered the adaptive security appliance is not supported. For example, if your management host is located on the outside interface, you can only initiate a management connection directly to the outside interface. The only exception to this rule is through a VPN connection, and entering the **management-access** command. For more information about the **management-access** command, see the *Cisco ASA 5500 Series Command Reference*.

### Detailed Steps

To configure SSH access, perform the following steps:

|        | Command                                                                                                                                     | Purpose                                                                                                                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto key generate rsa modulus</b> <i>modulus_size</i><br><br><b>Example:</b><br>hostname(config)# crypto key generate rsa modulus 1024 | Generates an RSA key pair, which is required for SSH.<br><br>The modulus (in bits) is 512, 768, 1024, or 2048. The larger the key modulus size you specify, the longer it takes to generate an RSA. We recommend a value of 1024. |
| Step 2 | <b>write mem</b><br><br><b>Example:</b><br>hostname(config)# write mem                                                                      | Saves the RSA keys to persistent flash memory.                                                                                                                                                                                    |

|               | Command                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                      |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <b>ssh</b> <i>source_IP_address mask source_interface</i><br><br><b>Example:</b><br><pre>hostname(config)# ssh 192.168.1.2 255.255.255.255 inside</pre> | Identifies the IP addresses from which the adaptive security appliance accepts connections. Make sure that you perform this step for each address or subnet.<br><br>The adaptive security appliance accepts SSH connections from all interfaces, including the one with the lowest security level.                                                           |
| <b>Step 4</b> | <b>ssh timeout</b> <i>minutes</i><br><br><b>Example:</b><br><pre>hostname(config)# ssh timeout 30</pre>                                                 | (Optional) Sets the duration for how long an SSH session can be idle before the adaptive security appliance disconnects the session.<br><br>Sets the timeout from 1 to 60 minutes. The default is 5 minutes. The default duration is too short in most cases and should be increased until all preproduction testing and troubleshooting has been completed. |

## Examples

The following example generates RSA keys and allows a host on the inside interface with an address of 192.168.1.2 to access the adaptive security appliance:

```
hostname(config)# crypto key generate rsa modulus 1024
hostname(config)# write mem
hostname(config)# ssh 192.168.1.2 255.255.255.255 inside
hostname(config)# ssh 192.168.1.2 255.255.255.255 inside
hostname(config)# ssh timeout 30
```

The following example allows all users on the 192.168.3.0 network to access the adaptive security appliance on the inside interface:

```
hostname(config)# ssh 192.168.3.0 255.255.255.0 inside
```

By default, SSH allows both Versions 1 and 2. The following example specifies the version number:

```
hostname(config)# ssh version version_number
```

The *version\_number* can be 1 or 2.

## Using an SSH Client

To gain access to the adaptive security appliance console using SSH, at the SSH client, enter the username **asa** and enter the login password set by the **password** command (see the [“Configuring the Hostname, Domain Name, and Passwords”](#) section on page 7-1).

When starting an SSH session, a dot (.) displays on the adaptive security appliance console before the SSH user authentication prompt appears, as follows:

```
hostname(config)# .
```

The display of the dot does not affect the functionality of SSH. The dot appears at the console when generating a server key or decrypting a message using private keys during SSH key exchange before user authentication occurs. These tasks can take up to two minutes or longer. The dot is a progress indicator that verifies that the adaptive security appliance is busy and has not hung.

## Configuring HTTPS Access for ASDM

To use ASDM, you need to enable the HTTPS server, and allow HTTPS connections to the adaptive security appliance. All of these tasks are completed if you use the **setup** command. This section describes how to manually configure ASDM access and how to log in to ASDM.

This section includes the following topics:

- [Enabling HTTPS Access, page 34-5](#)
- [Accessing ASDM from Your PC, page 34-6](#)

### Enabling HTTPS Access

To configure ASDM access, perform the following steps:

#### Restrictions

The adaptive security appliance allows a maximum of 5 concurrent ASDM instances per context, if available, with a maximum of 32 ASDM instances between all contexts.

Management access to an interface other than the one from which you entered the adaptive security appliance is not supported. For example, if your management host is located on the outside interface, you can only initiate a management connection directly to the outside interface. The only exception to this rule is through a VPN connection, and entering the **management-access** command. For more information about the **management-access** command, see the *Cisco ASA 5500 Series Command Reference*.

#### Detailed Steps

|        | Command                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                      |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>http</b> <i>source_IP_address mask</i><br><i>source_interface</i><br><br><b>Example:</b><br>hostname(config)# http 192.168.1.2<br>255.255.255.255 inside         | For each address or subnet, identifies the IP addresses from which the adaptive security appliance accepts HTTPS connections.                                                                                                                                |
| Step 2 | <b>http server enable</b> [ <i>port</i> ]<br><br><b>Example:</b><br>hostname(config)# http server enable 443                                                        | Enables the HTTPS server.<br><br>By default, the <i>port</i> is 443. If you change the port number, be sure to include it in the ASDM access URL. For example, if you change the port number to 444, enter the following:<br><br><b>https://10.1.1.1:444</b> |
| Step 3 | <b>asdm image disk</b> {0   1}:[ <i>path/</i> ] <i>filename</i><br><br><b>Example:</b><br>hostname(config)# asdm image disk{0   1}:[ <i>path/</i> ] <i>filename</i> | Specifies the location of the ASDM image.                                                                                                                                                                                                                    |

## Examples

The following example enables the HTTPS server and allows a host on the inside interface with an address of 192.168.1.2 to access ASDM:

```
hostname(config)# crypto key generate rsa modulus 1024  
hostname(config)# write mem  
hostname(config)# http server enable  
hostname(config)# http 192.168.1.2 255.255.255.255 inside
```

The following example allows all users on the 192.168.3.0 network to access ASDM on the inside interface:

```
hostname(config)# http 192.168.3.0 255.255.255.0 inside
```

## Accessing ASDM from Your PC

From a supported web browser on the adaptive security appliance network, enter the following URL:

```
https://interface_ip_address[:port]
```

In transparent firewall mode, enter the management IP address.

# Configuring CLI Parameters

This section includes the following topics:

- [Configuring a Login Banner, page 34-6](#)
- [Customizing a CLI Prompt, page 34-7](#)
- [Changing the Console Timeout Period, page 34-8](#)

## Configuring a Login Banner

You can configure a message to display when a user connects to the adaptive security appliance, before a user logs in, or before a user enters privileged EXEC mode.

### Restrictions

After a banner is added, Telnet or SSH sessions to adaptive security appliance may close if:

- There is not enough system memory available to process the banner message(s).
- A TCP write error occurs when attempting to display banner message(s).

### Guidelines

- From a security perspective, it is important that your banner discourage unauthorized access. Do not use the words “welcome” or “please,” as they appear to invite intruders in. The following banner sets the correct tone for unauthorized access:

```
You have logged in to a secure device. If you are not authorized to access this  
device,  
log out immediately or risk possible criminal consequences.
```

- See RFC 2196 for guidelines about banner messages.

## Detailed Steps

| Command                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>banner {exec   login   motd} text</b><br><br><b>Example:</b><br><pre>hostname(config)# banner motd Welcome to \$(hostname).</pre> | <p>Adds a banner to display at one of three times: when a user first connects (message-of-the-day (<b>motd</b>)), when a user logs in (<b>login</b>), and when a user accesses privileged EXEC mode (<b>exec</b>). When a user connects to the adaptive security appliance, the message-of-the-day banner appears first, followed by the login banner and prompts. After the user successfully logs in to the adaptive security appliance, the exec banner displays.</p> <p>To add more than one line, precede each line by the <b>banner</b> command.</p> <p>For the banner text:</p> <ul style="list-style-type: none"> <li>• Spaces are allowed but tabs cannot be entered using the CLI.</li> <li>• There is no length limit for banners other than those for RAM and flash memory.</li> <li>• You can dynamically add the hostname or domain name of the adaptive security appliance by including the strings <b>\$(hostname)</b> and <b>\$(domain)</b>.</li> <li>• If you configure a banner in the system configuration, you can use that banner text within a context by using the <b>\$(system)</b> string in the context configuration.</li> </ul> |

## Examples

For example, to add a message-of-the-day banner, enter:

```
hostname(config)# banner motd Welcome to $(hostname).
hostname(config)# banner motd Contact me at admin@example.com for any
hostname(config)# banner motd issues.
```

## Customizing a CLI Prompt

The CLI Prompt pane lets you customize the prompt used during CLI sessions. By default, the prompt shows the hostname of the adaptive security appliance. In multiple context mode, the prompt also displays the context name. You can display the following items in the CLI prompt.

|                 |                                                                |
|-----------------|----------------------------------------------------------------|
| <b>context</b>  | (Multiple mode only) Displays the name of the current context. |
| <b>domain</b>   | Displays the domain name.                                      |
| <b>hostname</b> | Displays the hostname.                                         |

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>priority</b> | Displays the failover priority as pri (primary) or sec (secondary).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>state</b>    | Displays the traffic-passing state of the unit. The following values are displayed for the state: <ul style="list-style-type: none"> <li>act—Failover is enabled, and the unit is actively passing traffic.</li> <li>stby— Failover is enabled, and the unit is not passing traffic and is in a standby, failed, or other non-active state.</li> <li>actNoFailover—Failover is not enabled, and the unit is actively passing traffic.</li> <li>stbyNoFailover—Failover is not enabled, and the unit is not passing traffic. This might happen when there is an interface failure above the threshold on the standby unit.</li> </ul> |

### Detailed Steps

| Command                                                                    | Purpose                    |
|----------------------------------------------------------------------------|----------------------------|
| <b>prompt</b> {[hostname] [context] [domain]<br>[slot] [state] [priority]} | Customizes the CLI prompt. |
| <b>Example:</b><br>hostname(config)# firewall transparent                  |                            |

## Changing the Console Timeout Period

To change the console timeout period, or the duration of time the management console remains active before automatically shutting down, perform the following steps.

### Detailed Steps

| Command                                                | Purpose                                                                                                                                                              |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>console timeout</b> <i>number</i>                   | Specifies the idle time in minutes (0 through 60) after which the console session ends. The default timeout is 0, which means the console session will not time out. |
| <b>Example:</b><br>hostname(config)# console timeout 0 |                                                                                                                                                                      |

## Configuring ICMP Access

By default, you can send ICMP packets to any adaptive security appliance interface using either IPv4 or IPv6. ICMP in IPv6 functions the same as ICMP in IPv4. ICMPv6 generates error messages, such as ICMP destination unreachable messages and informational messages like ICMP echo request and reply messages. Additionally ICMP packets in IPv6 are used in the IPv6 neighbor discovery process and path MTU discovery.

By default, the adaptive security appliance does not respond to ICMP echo requests directed to a broadcast address. You can protect the adaptive security appliance from attacks by limiting the addresses of hosts and networks that are allowed to have ICMP access to the adaptive security appliance.

The adaptive security appliance only responds to ICMP traffic sent to the interface that traffic comes in on; you cannot send ICMP traffic through an interface to a far interface.

**Note**

For allowing ICMP traffic *through* the adaptive security appliance, see [Chapter 32, “Configuring Access Rules.”](#)

We recommend you always grant permission for the ICMP unreachable message type (type 3). Denying ICMP unreachable messages disables ICMP Path MTU discovery, which can halt IPsec and PPTP traffic. See RFC 1195 and RFC 1435 for details about Path MTU Discovery.

If you configure ICMP rules, then the adaptive security appliance uses a first match to the ICMP traffic followed by an implicit deny all. That is, if the first matched entry is a permit entry, the ICMP packet continues to be processed. If the first matched entry is a deny entry or an entry is not matched, the adaptive security appliance discards the ICMP packet and generates a syslog message. An exception is when an ICMP rule is not configured; in that case, a permit statement is assumed.

To configure ICMP access rules, perform the following steps.

**Detailed Steps**

| Command                                                                                                                                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| (For IPv4)<br><br><b>icmp</b> { <b>permit</b>   <b>deny</b> } { <b>host</b> <i>ip_address</i>   <i>ip_address mask</i>   <b>any</b> } [ <i>icmp_type</i> ]<br><i>interface_name</i><br><br><b>Example:</b><br>hostname(config)# icmp deny host 10.1.1.15 inside | Creates an IPv4 ICMP access rule. If you do not specify an <i>icmp_type</i> , all types are identified. You can enter the number or the name. To control ping, specify echo-reply (0) (adaptive security appliance-to-host) or echo (8) (host-to-adaptive security appliance). See the “ <a href="#">ICMP Types</a> ” section on <a href="#">page B-15</a> for a list of ICMP types. |
| (For IPv6)<br><br><b>ipv6 icmp</b> { <b>permit</b>   <b>deny</b> } { <i>ipv6-prefix/prefix-length</i>   <b>any</b>   <b>host</b> <i>ipv6-address</i> } [ <i>icmp_type</i> ] <i>interface_name</i><br><br><b>Example:</b><br>hostname(config)#                   | Creates an IPv6 ICMP access rule. If you do not specify an <i>icmp_type</i> , all types are identified. You can enter the number or the name. To control ping, specify echo-reply (0) (adaptive security appliance-to-host) or echo (8) (host-to-adaptive security appliance). See the “ <a href="#">ICMP Types</a> ” section on <a href="#">page B-15</a> for a list of ICMP types. |

**Examples**

For example, to allow all hosts except the one at 10.1.1.15 to use ICMP to the inside interface, enter the following commands:

```
hostname(config)# icmp deny host 10.1.1.15 inside
hostname(config)# icmp permit any inside
```

To allow the host at 10.1.1.15 to use only ping to the inside interface, enter the following commands:

```
hostname(config)# icmp permit host 10.1.1.15 inside
```

The following example denies all ping requests and permits all Packet Too Big messages (to support Path MTU Discovery) at the outside interface:

```
hostname(config)# ipv6 icmp deny any echo-reply outside
hostname(config)# ipv6 icmp permit any packet-too-big outside
```

The following example permits host 2000:0:0:4::2 or hosts on prefix 2001::/64 to ping the outside interface:

```
hostname(config)# ipv6 icmp permit host 2000:0:0:4::2 echo-reply outside
hostname(config)# ipv6 icmp permit 2001::/64 echo-reply outside
hostname(config)# ipv6 icmp permit any packet-too-big outside
```

## Configuring Management Access Over a VPN Tunnel

If your VPN tunnel terminates on one interface, but you want to manage the adaptive security appliance by accessing a different interface, you can identify that interface as a management-access interface. For example, if you enter the adaptive security appliance from the outside interface, this feature lets you connect to the inside interface using ASDM, SSH, Telnet, or SNMP; or you can ping the inside interface when entering from the outside interface. Management access is available via the following VPN tunnel types: IPsec clients, IPsec LAN-to-LAN, and the AnyConnect SSL VPN client.

### Restrictions

You can define only one management-access interface.

### Detailed Steps

| Command                                                       | Purpose                                                                                                                                                                 |
|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>management access</b> <i>management_interface</i>          | The <i>management_interface</i> specifies the name of the management interface you want to access when entering the adaptive security appliance from another interface. |
| <b>Example:</b><br>hostname(config)# management access inside |                                                                                                                                                                         |

## Configuring AAA for System Administrators

This section describes how to enable authentication and command authorization for system administrators. Before you configure AAA for system administrators, first configure the local database or AAA server according to [Chapter 33, “AAA Server and Local Database Support.”](#)

This section includes the following topics:

- [Configuring Authentication for CLI and ASDM Access, page 34-11](#)
- [Configuring Authentication To Access Privileged EXEC Mode \(the enable Command\), page 34-12](#)
- [Limiting User CLI and ASDM Access with Management Authorization, page 34-13](#)
- [Configuring Command Authorization, page 34-14](#)
- [Configuring Management Access Accounting, page 34-25](#)
- [Viewing the Current Logged-In User, page 34-26](#)

- [Recovering from a Lockout, page 34-27](#)

## Configuring Authentication for CLI and ASDM Access

If you enable CLI authentication, the adaptive security appliance prompts you for your username and password to log in. After you enter your information, you have access to user EXEC mode.

To enter privileged EXEC mode, enter the **enable** command or the **login** command (if you are using the local database only).

If you configure **enable** authentication (see the “[Configuring Authentication for the enable Command](#)” section on page 34-12), the adaptive security appliance prompts you for your username and password. If you do not configure **enable** authentication, enter the system enable password when you enter the **enable** command (set by the **enable password** command). However, if you do not use **enable** authentication, after you enter the **enable** command, you are no longer logged in as a particular user. To maintain your username, use **enable** authentication.

For authentication using the local database, you can use the **login** command, which maintains the username but requires no configuration to turn on authentication.

### Note

Before the adaptive security appliance can authenticate a Telnet, SSH, or HTTP user, you must first configure access to the adaptive security appliance. See the “[Configuring Device Access for ASDM, Telnet, or SSH](#)” section on page 34-1. This configuration identifies the IP addresses that are allowed to communicate with the adaptive security appliance.

### Detailed Steps

| Command                                                                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>aaa authentication {telnet   ssh   http   serial} console {LOCAL   server_group [LOCAL]}</pre> <p><b>Example:</b></p> <pre>hostname(config)# aaa authentication telnet console LOCAL</pre> | <p>The <b>http</b> keyword authenticates the ASDM client that accesses the adaptive security appliance using HTTPS. You only need to configure HTTP authentication if you want to use a AAA server. By default, ASDM uses the local database for authentication even if you do not configure this command. HTTP management authentication does not support the SDI protocol for a AAA server group.</p> <p>If you use a AAA server group for authentication, you can configure the adaptive security appliance to use the local database as a fallback method if the AAA server is unavailable. Specify the server group name followed by <b>LOCAL</b> (<b>LOCAL</b> is case sensitive). We recommend that you use the same username and password in the local database as the AAA server because the adaptive security appliance prompt does not give any indication which method is being used.</p> <p>You can alternatively use the local database as your main method of authentication (with no fallback) by entering <b>LOCAL</b> alone.</p> |

# Configuring Authentication To Access Privileged EXEC Mode (the enable Command)

You can configure the adaptive security appliance to authenticate users with a AAA server or the local database when they enter the **enable** command. Alternatively, users are automatically authenticated with the local database when they enter the **login** command, which also accesses privileged EXEC mode depending on the user level in the local database.

This section includes the following topics:

- [Configuring Authentication for the enable Command, page 34-12](#)
- [Authenticating Users with the login Command, page 34-12](#)

## Configuring Authentication for the enable Command

You can configure the adaptive security appliance to authenticate users when they enter the **enable** command. If you do not authenticate the **enable** command, when you enter **enable**, the adaptive security appliance prompts for the system enable password (set by the **enable password** command), and you are no longer logged in as a particular user. Applying authentication to the **enable** command maintains the username. This feature is particularly useful when you perform command authorization, where usernames are important to determine the commands a user can enter.

### Detailed Steps

| Command                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>aaa authentication enable console {LOCAL   server_group [LOCAL]}</code>               | Authenticates users who enter the <b>enable</b> command. The user is prompted for the username and password.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <p><b>Example:</b></p> <pre>hostname(config)# aaa authentication enable console LOCAL</pre> | <p>If you use a AAA server group for authentication, you can configure the adaptive security appliance to use the local database as a fallback method if the AAA server is unavailable. Specify the server group name followed by <b>LOCAL</b> (<b>LOCAL</b> is case sensitive). We recommend that you use the same username and password in the local database as the AAA server because the adaptive security appliance prompt does not give any indication which method is being used.</p> <p>You can alternatively use the local database as your main method of authentication (with no fallback) by entering <b>LOCAL</b> alone.</p> |

## Authenticating Users with the login Command

From user EXEC mode, you can log in as any username in the local database using the **login** command.

This feature allows users to log in with their own username and password to access privileged EXEC mode, so you do not have to give out the system enable password to everyone. To allow users to access privileged EXEC mode (and all commands) when they log in, set the user privilege level to 2 (the default) through 15. If you configure local command authorization, then the user can only enter commands assigned to that privilege level or lower. See the [“Configuring Local Command Authorization” section on page 34-16](#) for more information.

**Caution**

If you add users to the local database who can gain access to the CLI and whom you do not want to enter privileged EXEC mode, you should configure command authorization. Without command authorization, users can access privileged EXEC mode (and all commands) at the CLI using their own password if their privilege level is 2 or greater (2 is the default). Alternatively, you can use a AAA server for authentication, or you can set all local users to level 1 so you can control who can use the system enable password to access privileged EXEC mode.

To log in as a user from the local database, enter the following command:

```
hostname> login
```

The adaptive security appliance prompts for your username and password. After you enter your password, the adaptive security appliance places you in the privilege level that the local database specifies.

## Limiting User CLI and ASDM Access with Management Authorization

If you configure CLI or **enable** authentication, you can limit a local user, RADIUS, TACACS+, or LDAP user (if you map LDAP attributes to RADIUS attributes) from accessing the CLI, ASDM, or the **enable** command.

**Note**

Serial access is not included in management authorization, so if you configure **aaa authentication serial console**, then any user who authenticates can access the console port.

### Detailed Steps

To configure management authorization, perform the following steps:

**Step 1** To enable management authorization, enter the following command:

```
hostname(config)# aaa authorization exec authentication-server
```

This command also enables support of administrative user privilege levels from RADIUS, which can be used in conjunction with local command privilege levels for command authorization. See the [“Configuring Local Command Authorization” section on page 34-16](#) for more information.

**Step 2** To configure the user for management authorization, see the following requirements for each AAA server type or local user:

- RADIUS or LDAP (mapped) users—Use the IETF RADIUS numeric Service-Type attribute which maps to one of the following values. (To map LDAP attributes, see the [“LDAP Attribute Mapping for Authorization” section on page 33-18](#).)
  - Service-Type 6 (Administrative)—Allows full access to any services specified by the **aaa authentication console** commands.
  - Service-Type 7 (NAS prompt)—Allows access to the CLI when you configure the **aaa authentication {telnet | ssh} console** command, but denies ASDM configuration access if you configure the **aaa authentication http console** command. ASDM monitoring access is allowed. If you configure **enable** authentication with the **aaa authentication enable console** command, the user cannot access privileged EXEC mode using the **enable** command.

- Service-Type 5 (Outbound)—Denies management access. The user cannot use any services specified by the **aaa authentication console** commands (excluding the **serial** keyword; serial access is allowed). Remote access (IPSec and SSL) users can still authenticate and terminate their remote access sessions.
  - TACACS+ users—Authorization is requested with “service=shell,” and the server responds with PASS or FAIL.
    - PASS, privilege level 1—Allows access to ASDM, with limited read-only access to the configuration and monitoring sections, and access for **show** commands that are privilege level 1 only.
    - PASS, privilege level 2 and higher—Allows access to the CLI when you configure the **aaa authentication {telnet | ssh} console** command, but denies ASDM configuration access if you configure the **aaa authentication http console** command. ASDM monitoring access is allowed. If you configure **enable** authentication with the **aaa authentication enable console** command, the user cannot access privileged EXEC mode using the **enable** command. You are not allowed to access privileged EXEC mode using the **enable** command if your enable privilege level is set to 14 or less.
    - FAIL—Denies management access. You cannot use any services specified by the **aaa authentication console** commands (excluding the **serial** keyword; serial access is allowed).
  - Local users—Set the **service-type** command. See the [“Configuring the Local Database” section on page 33-8](#). By default, the **service-type** is **admin**, which allows full access to any services specified by the **aaa authentication console** commands.
- 

## Configuring Command Authorization

If you want to control the access to commands, the adaptive security appliance lets you configure command authorization, where you can determine which commands that are available to a user. By default when you log in, you can access user EXEC mode, which offers only minimal commands. When you enter the **enable** command (or the **login** command when you use the local database), you can access privileged EXEC mode and advanced commands, including configuration commands.

This section includes the following topics:

- [Command Authorization Overview, page 34-14](#)
- [Configuring Local Command Authorization, page 34-16](#)
- [Configuring TACACS+ Command Authorization, page 34-21](#)

## Command Authorization Overview

This section describes command authorization and includes the following topics:

- [Supported Command Authorization Methods, page 34-15](#)
- [About Preserving User Credentials, page 34-15](#)
- [Security Contexts and Command Authorization, page 34-16](#)

## Supported Command Authorization Methods

You can use one of two command authorization methods:

- **Local privilege levels**—Configure the command privilege levels on the adaptive security appliance. When a local, RADIUS, or LDAP (if you map LDAP attributes to RADIUS attributes) user authenticates for CLI access, the adaptive security appliance places that user in the privilege level that is defined by the local database, RADIUS, or LDAP server. The user can access commands at the user's privilege level and below. Note that all users access user EXEC mode when they first log in (commands at level 0 or 1). The user needs to authenticate again with the **enable** command to access privileged EXEC mode (commands at level 2 or higher), or they can log in with the **login** command (local database only).

### Note

You can use local command authorization without any users in the local database and without CLI or **enable** authentication. Instead, when you enter the **enable** command, you enter the system enable password, and the adaptive security appliance places you in level 15. You can then create enable passwords for every level, so that when you enter **enable n** (2 to 15), the adaptive security appliance places you in level *n*. These levels are not used unless you turn on local command authorization (see “[Configuring Local Command Authorization](#)”). (See the *Cisco ASA 5500 Series Command Reference* for more information about the **enable** command.)

- **TACACS+ server privilege levels**—On the TACACS+ server, configure the commands that a user or group can use after they authenticate for CLI access. Every command that a user enters at the CLI is checked with the TACACS+ server.

## About Preserving User Credentials

When a user logs into the adaptive security appliance, they are required to provide a username and password for authentication. The adaptive security appliance retains these session credentials in case further authentication is needed later in the session.

When the following configurations are in place, a user needs only to authenticate with the local server upon login. Subsequent serial authorization uses the saved credentials. The user is also prompted for the privilege level 15 password. When exiting privileged mode, the user is authenticated again. User credentials are not retained in privileged mode.

- Local server is configured to authenticate user access.
- Privilege level 15 command access is configured to require a password.
- User's account is configured for serial only authorization (no access to console or ASDM).
- User's account is configured for privilege level 15 command access.

The following table shows how credentials are used in this case by the adaptive security appliance.

| Credentials required     | Username and Password Authentication | Serial Authorization | Privileged Mode Command Authorization | Privileged Mode Exit Authorization |
|--------------------------|--------------------------------------|----------------------|---------------------------------------|------------------------------------|
| Username                 | Yes                                  | No                   | No                                    | Yes                                |
| Password                 | Yes                                  | No                   | No                                    | Yes                                |
| Privileged Mode Password | No                                   | No                   | Yes                                   | No                                 |

## Security Contexts and Command Authorization

The following are important points to consider when implementing command authorization with multiple security contexts:

- AAA settings are discrete per context, not shared between contexts.

When configuring command authorization, you must configure each security context separately. This provides you the opportunity to enforce different command authorizations for different security contexts.

When switching between security contexts, administrators should be aware that the commands permitted for the username specified when they login may be different in the new context session or that command authorization may not be configured at all in the new context. Failure to understand that command authorizations may differ between security contexts could confuse an administrator. This behavior is further complicated by the next point.

- New context sessions started with the **changeto** command always use the default “enable\_15” username as the administrator identity, regardless of what username was used in the previous context session. This behavior can lead to confusion if command authorization is not configured for the enable\_15 user or if authorizations are different for the enable\_15 user than for the user in the previous context session.

This behavior also affects command accounting, which is useful only if you can accurately associate each command that is issued with a particular administrator. Because all administrators with permission to use the **changeto** command can use the enable\_15 username in other contexts, command accounting records may not readily identify who was logged in as the enable\_15 username. If you use different accounting servers for each context, tracking who was using the enable\_15 username requires correlating the data from several servers.

When configuring command authorization, consider the following:

- An administrator with permission to use the **changeto** command effectively has permission to use all commands permitted to the enable\_15 user in each of the other contexts.
- If you intend to authorize commands differently per context, ensure that in each context the enable\_15 username is denied use of commands that are also denied to administrators who are permitted use of the **changeto** command.

When switching between security contexts, administrators can exit privileged EXEC mode and enter the **enable** command again to use the username they need.

### Note

The system execution space does not support AAA commands; therefore, command authorization is not available in the system execution space.

## Configuring Local Command Authorization

Local command authorization lets you assign commands to one of 16 privilege levels (0 to 15). By default, each command is assigned either to privilege level 0 or 15. You can define each user to be at a specific privilege level, and each user can enter any command at their privilege level or below. The adaptive security appliance supports user privilege levels defined in the local database, a RADIUS server, or an LDAP server (if you map LDAP attributes to RADIUS attributes. See the [“LDAP Attribute Mapping for Authorization”](#) section on page 33-18.)

This section includes the following topics:

- [Local Command Authorization Prerequisites](#), page 34-17

- [Default Command Privilege Levels, page 34-17](#)
- [Assigning Privilege Levels to Commands and Enabling Authorization, page 34-18](#)
- [Viewing Command Privilege Levels, page 34-20](#)

### Local Command Authorization Prerequisites

Complete the following tasks as part of your command authorization configuration:

- Configure **enable** authentication. (See the [“Configuring Authentication for CLI and ASDM Access” section on page 34-11.](#))

**enable** authentication is essential to maintain the username after the user accesses the **enable** command.

Alternatively, you can use the **login** command (which is the same as the **enable** command with authentication; for the local database only), which requires no configuration. We do not recommend this option because it is not as secure as **enable** authentication.

You can also use CLI authentication, but it is not required.

- See the following prerequisites for each user type:
  - Local database users—Configure each user in the local database at a privilege level from 0 to 15.  
To configure the local database, see the [“Configuring the Local Database” section on page 33-8.](#)
  - RADIUS users—Configure the user with Cisco VSA CVPN3000-Privilege-Level with a value between 0 and 15.
  - LDAP users—Configure the user with a privilege level between 0 and 15, and then map the LDAP attribute to Cisco VAS CVPN3000-Privilege-Level according to the [“LDAP Attribute Mapping for Authorization” section on page 33-18.](#)

### Default Command Privilege Levels

By default, the following commands are assigned to privilege level 0. All other commands are at level 15.

- **show checksum**
- **show curpriv**
- **enable**
- **help**
- **show history**
- **login**
- **logout**
- **pager**
- **show pager**
- **clear pager**
- **quit**
- **show version**

If you move any configure mode commands to a lower level than 15, be sure to move the **configure** command to that level as well, otherwise, the user will not be able to enter configuration mode.

To view all privilege levels, see the [“Viewing Command Privilege Levels” section on page 34-20.](#)

## Assigning Privilege Levels to Commands and Enabling Authorization

This section assigns a command to a new privilege level, and enables authorization.

## Detailed Steps

|        | Command                                                                                                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p><b>privilege</b> [<b>show</b>   <b>clear</b>   <b>cmd</b>] <b>level</b> <i>level</i><br/> [<b>mode</b> {<b>enable</b>   <b>cmd</b>}] <b>command</b> <i>command</i></p> <p><b>Example:</b><br/> hostname(config)# privilege show level 5<br/> command filter</p> | <p>Assigns a command to a privilege level.</p> <p>Repeat this command for each command you want to reassign.</p> <p>See the following information about the options in this command:</p> <ul style="list-style-type: none"> <li>• <b>show</b>   <b>clear</b>   <b>cmd</b>—These optional keywords let you set the privilege only for the show, clear, or configure form of the command. The configure form of the command is typically the form that causes a configuration change, either as the unmodified command (without the <b>show</b> or <b>clear</b> prefix) or as the <b>no</b> form. If you do not use one of these keywords, all forms of the command are affected.</li> <li>• <b>level</b> <i>level</i>—A level between 0 and 15.</li> <li>• <b>mode</b> {<b>enable</b>   <b>configure</b>}—If a command can be entered in user EXEC/privileged EXEC mode as well as configuration mode, and the command performs different actions in each mode, you can set the privilege level for these modes separately: <ul style="list-style-type: none"> <li>– <b>enable</b>—Specifies both user EXEC mode and privileged EXEC mode.</li> <li>– <b>configure</b>—Specifies configuration mode, accessed using the <b>configure terminal</b> command.</li> </ul> </li> <li>• <b>command</b> <i>command</i>—The command you are configuring. You can only configure the privilege level of the <i>main</i> command. For example, you can configure the level of all <b>aaa</b> commands, but not the level of the <b>aaa authentication</b> command and the <b>aaa authorization</b> command separately.</li> </ul> |
| Step 2 | <p><b>aaa authorization exec authentication-server</b></p> <p><b>Example:</b><br/> hostname(config)# aaa authorization exec authentication-server</p>                                                                                                              | <p>Supports administrative user privilege levels from RADIUS.</p> <p>Without this command, the adaptive security appliance only supports privilege levels for local database users and defaults all other types of users to level 15.</p> <p>This command also enables management authorization for local, RADIUS, LDAP (mapped), and TACACS+ users. See the <a href="#">“Limiting User CLI and ASDM Access with Management Authorization”</a> section on page 34-13 for more information.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 3 | <p><b>aaa authorization command LOCAL</b></p> <p><b>Example:</b><br/> hostname(config)# aaa authorization command LOCAL</p>                                                                                                                                        | <p>Enables the use of local command privilege levels, which can be checked against the privilege level of users in the local database, RADIUS server, or LDAP server (with mapped attributes).</p> <p>When you set command privilege levels, command authorization does not take place unless you configure command authorization with this command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Examples

For example, the **filter** command has the following forms:

- **filter** (represented by the **configure** option)
- **show running-config filter**
- **clear configure filter**

You can set the privilege level separately for each form, or set the same privilege level for all forms by omitting this option. For example, set each form separately as follows.

```
hostname(config)# privilege show level 5 command filter
hostname(config)# privilege clear level 10 command filter
hostname(config)# privilege cmd level 10 command filter
```

Alternatively, you can set all filter commands to the same level:

```
hostname(config)# privilege level 5 command filter
```

The **show privilege** command separates the forms in the display.

The following example shows the use of the **mode** keyword. The **enable** command must be entered from user EXEC mode, while the **enable password** command, which is accessible in configuration mode, requires the highest privilege level.

```
hostname(config)# privilege cmd level 0 mode enable command enable
hostname(config)# privilege cmd level 15 mode cmd command enable
hostname(config)# privilege show level 15 mode cmd command enable
```

This example shows an additional command, the **configure** command, that uses the **mode** keyword:

```
hostname(config)# privilege show level 5 mode cmd command configure
hostname(config)# privilege clear level 15 mode cmd command configure
hostname(config)# privilege cmd level 15 mode cmd command configure
hostname(config)# privilege cmd level 15 mode enable command configure
```

Note

This last line is for the **configure terminal** command.

Viewing Command Privilege Levels

The following commands let you view privilege levels for commands.

| Command                                                     | Purpose                                                                               |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------|
| <b>show running-config all privilege all</b>                | Shows all commands.                                                                   |
| <b>show running-config privilege level <i>level</i></b>     | Shows commands for a specific level. The <i>level</i> is an integer between 0 and 15. |
| <b>show running-config privilege command <i>command</i></b> | Shows the level of a specific command.                                                |

Examples

For example, for the **show running-config all privilege all** command, the system displays the current assignment of each CLI command to a privilege level. The following is sample output from the command.

```
hostname(config)# show running-config all privilege all
privilege show level 15 command aaa
```

```
privilege clear level 15 command aaa
privilege configure level 15 command aaa
privilege show level 15 command aaa-server
privilege clear level 15 command aaa-server
privilege configure level 15 command aaa-server
privilege show level 15 command access-group
privilege clear level 15 command access-group
privilege show level 15 command access-list
privilege clear level 15 command access-list
privilege configure level 15 command access-list
privilege show level 15 command activation-key
privilege configure level 15 command activation-key
....
```

The following command displays the command assignments for privilege level 10:

```
hostname(config)# show running-config privilege level 10
privilege show level 10 command aaa
```

The following command displays the command assignment for the **access-list** command:

```
hostname(config)# show running-config privilege command access-list
privilege show level 15 command access-list
privilege clear level 15 command access-list
privilege configure level 15 command access-list
```

## Configuring TACACS+ Command Authorization

If you enable TACACS+ command authorization, and a user enters a command at the CLI, the adaptive security appliance sends the command and username to the TACACS+ server to determine if the command is authorized.

When configuring command authorization with a TACACS+ server, do not save your configuration until you are sure it works the way you want. If you get locked out because of a mistake, you can usually recover access by restarting the adaptive security appliance. If you still get locked out, see the [“Recovering from a Lockout” section on page 34-27](#).

Be sure that your TACACS+ system is completely stable and reliable. The necessary level of reliability typically requires that you have a fully redundant TACACS+ server system and fully redundant connectivity to the adaptive security appliance. For example, in your TACACS+ server pool, include one server connected to interface 1, and another to interface 2. You can also configure local command authorization as a fallback method if the TACACS+ server is unavailable. In this case, you need to configure local users and command privilege levels according to the [“Configuring Command Authorization” section on page 34-14](#).

This section includes the following topics:

- [TACACS+ Command Authorization Prerequisites, page 34-21](#)
- [Configuring Commands on the TACACS+ Server, page 34-22](#)
- [Enabling TACACS+ Command Authorization, page 34-24](#)

### TACACS+ Command Authorization Prerequisites

Complete the following tasks as part of your command authorization configuration:

- Configure CLI authentication (see the [“Configuring Local Command Authorization” section on page 34-16](#)).

- Configure **enable** authentication (see the “[Configuring Authentication To Access Privileged EXEC Mode \(the enable Command\)](#)” section on page 34-12).

## Configuring Commands on the TACACS+ Server

You can configure commands on a Cisco Secure Access Control Server (ACS) TACACS+ server as a shared profile component, for a group, or for individual users. For third-party TACACS+ servers, see your server documentation for more information about command authorization support.

See the following guidelines for configuring commands in Cisco Secure ACS Version 3.1; many of these guidelines also apply to third-party servers:

- The adaptive security appliance sends the commands to be authorized as “shell” commands, so configure the commands on the TACACS+ server as shell commands.

**Note** Cisco Secure ACS might include a command type called “pix-shell.” Do not use this type for adaptive security appliance command authorization.

- The first word of the command is considered to be the main command. All additional words are considered to be arguments, which need to be preceded by **permit** or **deny**.

For example, to allow the **show running-configuration aaa-server** command, add **show running-configuration** to the command field, and type **permit aaa-server** in the arguments field.

- You can permit all arguments of a command that you do not explicitly deny by checking the **Permit Unmatched Args** check box.

For example, you can configure just the **show** command, and then all the **show** commands are allowed. We recommend using this method so that you do not have to anticipate every variant of a command, including abbreviations and **?**, which shows CLI usage (see [Figure 34-1](#)).

**Figure 34-1** *Permitting All Related Commands*

The screenshot shows a configuration window for a TACACS+ server. On the left, there is a text area labeled 'show' under a blue header. On the right, there is a text area for arguments, which is currently empty. Above the arguments area is a checkbox labeled 'Permit Unmatched Args' which is checked. Below these two areas is a small input field and two buttons: 'Add Command' and 'Remove Command'. A vertical label '114412' is positioned to the right of the main configuration area.

- For commands that are a single word, you *must* permit unmatched arguments, even if there are no arguments for the command, for example **enable** or **help** (see [Figure 34-2](#)).

**Figure 34-2**      **Permitting Single Word Commands**

The screenshot shows a configuration window with two main text areas. The left area, labeled 'Commands', contains the word 'enable'. The right area, labeled 'Arguments', is empty. Above the 'Arguments' area is a checkbox labeled 'Permit Unmatched Args' which is checked. Below the text areas are two buttons: 'Add Command' and 'Remove Command'. A small text '114411' is visible on the right side of the window.

- To disallow some arguments, enter the arguments preceded by **deny**.

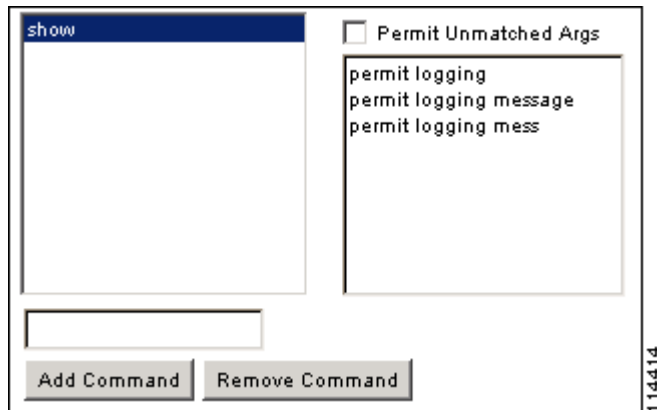

For example, to allow **enable**, but not **enable password**, enter **enable** in the commands field, and **deny password** in the arguments field. Be sure to check the **Permit Unmatched Args** check box so that **enable** alone is still allowed (see [Figure 34-3](#)).

**Figure 34-3**      **Disallowing Arguments**

The screenshot shows a configuration window similar to Figure 34-2. The 'Commands' field contains 'enable'. The 'Arguments' field now contains 'deny password'. The 'Permit Unmatched Args' checkbox remains checked. The 'Add Command' and 'Remove Command' buttons are at the bottom. A small text '114410' is visible on the right side of the window.

- When you abbreviate a command at the command line, the adaptive security appliance expands the prefix and main command to the full text, but it sends additional arguments to the TACACS+ server as you enter them.

For example, if you enter **sh log**, then the adaptive security appliance sends the entire command to the TACACS+ server, **show logging**. However, if you enter **sh log mess**, then the adaptive security appliance sends **show logging mess** to the TACACS+ server, and not the expanded command **show logging message**. You can configure multiple spellings of the same argument to anticipate abbreviations (see [Figure 34-4](#)).

**Figure 34-4 Specifying Abbreviations**

- We recommend that you allow the following basic commands for all users:
  - **show checksum**
  - **show curpriv**
  - **enable**
  - **help**
  - **show history**
  - **login**
  - **logout**
  - **pager**
  - **show pager**
  - **clear pager**
  - **quit**
  - **show version**

### Enabling TACACS+ Command Authorization

Before you enable TACACS+ command authorization, be sure that you are logged into the adaptive security appliance as a user that is defined on the TACACS+ server, and that you have the necessary command authorization to continue configuring the adaptive security appliance. For example, you should log in as an admin user with all commands authorized. Otherwise, you could become unintentionally locked out.

## Detailed Steps

| Command                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>aaa authorization command</b><br><code>tacacs+_server_group [LOCAL]</code>           | Performs command authorization using a TACACS+ server.<br><br>You can configure the adaptive security appliance to use the local database as a fallback method if the TACACS+ server is unavailable. To enable fallback, specify the server group name followed by <b>LOCAL</b> ( <b>LOCAL</b> is case sensitive). We recommend that you use the same username and password in the local database as the TACACS+ server because the adaptive security appliance prompt does not give any indication which method is being used. Be sure to configure users in the local database (see the <a href="#">“Configuring the Local Database”</a> section on page 33-8) and command privilege levels (see the <a href="#">“Configuring Local Command Authorization”</a> section on page 34-16). |
| <b>Example:</b><br><pre>hostname(config)# aaa authorization command group_1 LOCAL</pre> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Configuring Management Access Accounting

You can configure accounting when users log in, when they enter the **enable** command, or when they issue commands.

### Prerequisites

You can only account for users that first authenticate with the adaptive security appliance, so configure authentication using the [“Configuring Authentication for CLI and ASDM Access”](#) section on page 34-11.

For information about configuring a AAA server group, see the [“Identifying AAA Server Groups and Servers”](#) section on page 33-11. For CLI access, you can use TACACS+ or RADIUS servers. For command accounting, you can only use TACACS+ servers.

## Detailed Steps

| Command                                                                                     | Purpose                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>aaa accounting {serial   telnet   ssh   enable} console server-tag</b>                   | Enables support for AAA accounting for administrative access.<br><br>Valid server group protocols are RADIUS and TACACS+.                                                                                                                                                                  |
| <b>Example:</b><br><pre>hostname(config)# aaa accounting telnet console group_1</pre>       |                                                                                                                                                                                                                                                                                            |
| <b>aaa accounting command [privilege level] server-tag</b>                                  | Enables command accounting. Only TACACS+ servers support command accounting.<br><br>Where <i>level</i> is the minimum privilege level and <i>server-tag</i> is the name of the TACACS+ server group that to which the adaptive security appliance should send command accounting messages. |
| <b>Example:</b><br><pre>hostname(config)# aaa accounting command privilege 15 group_1</pre> |                                                                                                                                                                                                                                                                                            |

## Viewing the Current Logged-In User

To view the current logged-in user, enter the following command:

```
hostname# show curpriv
```

See the following sample **show curpriv** command output. A description of each field follows.

```
hostname# show curpriv
Username : admin
Current privilege level : 15
Current Mode/s : P_PRIV
```

Table 34-1 describes the **show curpriv** command output.

**Table 34-1** *show curpriv Command Output Description*

| Field                   | Description                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username                | Username. If you are logged in as the default user, the name is enable_1 (user EXEC) or enable_15 (privileged EXEC).                                                                                        |
| Current privilege level | Level from 0 to 15. Unless you configure local command authorization and assign commands to intermediate privilege levels, levels 0 and 15 are the only levels that are used.                               |
| Current Mode/s          | Shows the access modes: <ul style="list-style-type: none"><li>• P_UNPR—User EXEC mode (levels 0 and 1)</li><li>• P_PRIV—Privileged EXEC mode (levels 2 to 15)</li><li>• P_CONF—Configuration mode</li></ul> |

## Recovering from a Lockout

In some circumstances, when you turn on command authorization or CLI authentication, you can be locked out of the adaptive security appliance CLI. You can usually recover access by restarting the adaptive security appliance. However, if you already saved your configuration, you might be locked out. [Table 34-2](#) lists the common lockout conditions and how you might recover from them.

**Table 34-2** CLI Authentication and Command Authorization Lockout Scenarios

| Feature                                                                                  | Lockout Condition                                                             | Description                                                                                  | Workaround: Single Mode                                                                                                                                                                                                   | Workaround: Multiple Mode                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Local CLI authentication                                                                 | No users in the local database                                                | If you have no users in the local database, you cannot log in, and you cannot add any users. | Log in and reset the passwords and <b>aaa</b> commands.                                                                                                                                                                   | Session into the adaptive security appliance from the switch. From the system execution space, you can change to the context and add a user.                                                                                                                                                                                                                                                                                                                 |
| TACACS+ command authorization<br>TACACS+ CLI authentication<br>RADIUS CLI authentication | Server down or unreachable and you do not have the fallback method configured | If the server is unreachable, then you cannot log in or enter any commands.                  | <ol style="list-style-type: none"> <li>1. Log in and reset the passwords and AAA commands.</li> <li>2. ## CHAPTER 35

# Configuring AAA Rules for Network Access

---

This chapter describes how to enable AAA (pronounced “triple A”) for network access.

For information about AAA for management access, see the [“Configuring AAA for System Administrators”](#) section on page 34-10.

This chapter includes the following sections:

- [AAA Performance, page 35-1](#)
- [Configuring Authentication for Network Access, page 35-1](#)
- [Configuring Authorization for Network Access, page 35-8](#)
- [Configuring Accounting for Network Access, page 35-14](#)
- [Using MAC Addresses to Exempt Traffic from Authentication and Authorization, page 35-16](#)

## AAA Performance

The adaptive security appliance uses “cut-through proxy” to significantly improve performance compared to a traditional proxy server. The performance of a traditional proxy server suffers because it analyzes every packet at the application layer of the OSI model. The adaptive security appliance cut-through proxy challenges a user initially at the application layer and then authenticates against standard AAA servers or the local database. After the adaptive security appliance authenticates the user, it shifts the session flow, and all traffic flows directly and quickly between the source and destination while maintaining session state information.

## Configuring Authentication for Network Access

This section includes the following topics:

- [Authentication Overview, page 35-2](#)
- [Enabling Network Access Authentication, page 35-4](#)
- [Enabling Secure Authentication of Web Clients, page 35-5](#)
- [Authenticating Directly with the Adaptive Security Appliance, page 35-6](#)

## Authentication Overview

The adaptive security appliance lets you configure network access authentication using AAA servers. This section includes the following topics:

- [One-Time Authentication, page 35-2](#)
- [Applications Required to Receive an Authentication Challenge, page 35-2](#)
- [Adaptive Security Appliance Authentication Prompts, page 35-2](#)
- [Static PAT and HTTP, page 35-3](#)
- [Enabling Network Access Authentication, page 35-4](#)

### One-Time Authentication

A user at a given IP address only needs to authenticate one time for all rules and types, until the authentication session expires. (See the **timeout uauth** command in the *Cisco ASA 5500 Series Command Reference* for timeout values.) For example, if you configure the adaptive security appliance to authenticate Telnet and FTP, and a user first successfully authenticates for Telnet, then as long as the authentication session exists, the user does not also have to authenticate for FTP.

### Applications Required to Receive an Authentication Challenge

Although you can configure the adaptive security appliance to require authentication for network access to any protocol or service, users can authenticate directly with HTTP, HTTPS, Telnet, or FTP only. A user must first authenticate with one of these services before the adaptive security appliance allows other traffic requiring authentication.

The authentication ports that the adaptive security appliance supports for AAA are fixed as follows:

- Port 21 for FTP
- Port 23 for Telnet
- Port 80 for HTTP
- Port 443 for HTTPS

### Adaptive Security Appliance Authentication Prompts

For Telnet and FTP, the adaptive security appliance generates an authentication prompt.

For HTTP, the adaptive security appliance uses basic HTTP authentication by default, and provides an authentication prompt. You can optionally configure the adaptive security appliance to redirect users to an internal web page where they can enter their username and password (configured with the **aaa authentication listener** command).

For HTTPS, the adaptive security appliance generates a custom login screen. You can optionally configure the adaptive security appliance to redirect users to an internal web page where they can enter their username and password (configured with the **aaa authentication listener** command).

Redirection is an improvement over the basic method because it provides an improved user experience when authenticating, and an identical user experience for HTTP and HTTPS in both Easy VPN and firewall modes. It also supports authenticating directly with the adaptive security appliance.

You might want to continue to use basic HTTP authentication if: you do not want the adaptive security appliance to open listening ports; if you use NAT on a router and you do not want to create a translation rule for the web page served by the adaptive security appliance; basic HTTP authentication might work better with your network. For example non-browser applications, like when a URL is embedded in email, might be more compatible with basic authentication.

After you authenticate correctly, the adaptive security appliance redirects you to your original destination. If the destination server also has its own authentication, the user enters another username and password. If you use basic HTTP authentication and need to enter another username and password for the destination server, then you need to configure the **virtual http** command.

**Note**

If you use HTTP authentication, by default the username and password are sent from the client to the adaptive security appliance in clear text; in addition, the username and password are sent on to the destination web server as well. See the [“Enabling Secure Authentication of Web Clients” section on page 35-5](#) for information to secure your credentials.

For FTP, a user has the option of entering the adaptive security appliance username followed by an at sign (@) and then the FTP username (name1@name2). For the password, the user enters the adaptive security appliance password followed by an at sign (@) and then the FTP password (password1@password2). For example, enter the following text.

```
name> user1@user2
password> letmein@he110
```

This feature is useful when you have cascaded firewalls that require multiple logins. You can separate several names and passwords by multiple at signs (@).

## Static PAT and HTTP

For HTTP authentication, the adaptive security appliance checks real ports when static PAT is configured. If it detects traffic destined for real port 80, regardless of the mapped port, the adaptive security appliance intercepts the HTTP connection and enforces authentication.

For example, assume that outside TCP port 889 is translated to port 80 (www) and that any relevant access lists permit the traffic:

```
object network obj-192.168.123.10-01
  host 192.168.123.10
  nat (inside,outside) static 10.48.66.155 service tcp 80 889
```

Then when users try to access 10.48.66.155 on port 889, the adaptive security appliance intercepts the traffic and enforces HTTP authentication. Users see the HTTP authentication page in their web browsers before the adaptive security appliance allows HTTP connection to complete.

If the local port is different than port 80, as in the following example:

```
object network obj-192.168.123.10-02
  host 192.168.123.10
  nat (inside,outside) static 10.48.66.155 service tcp 111 889
```

Then users do not see the authentication page. Instead, the adaptive security appliance sends to the web browser an error message indicating that the user must be authenticated prior using the requested service.

## Enabling Network Access Authentication

To enable network access authentication, perform the following steps:

- Step 1** Using the **aaa-server** command, identify your AAA servers. If you have already identified your AAA servers, continue to the next step.
- For more information about identifying AAA servers, see the [“Identifying AAA Server Groups and Servers” section on page 33-11](#).

- Step 2** Using the **access-list** command, create an access list that identifies the source addresses and destination addresses of traffic you want to authenticate. For details, see [Chapter 13, “Adding an Extended Access List.”](#)

The **permit** ACEs mark matching traffic for authentication, while **deny** entries exclude matching traffic from authentication. Be sure to include the destination ports for either HTTP, HTTPS, Telnet, or FTP in the access list because the user must authenticate with one of these services before other services are allowed through the adaptive security appliance.

- Step 3** To configure authentication, enter the following command:

```
hostname(config)# aaa authentication match acl_name interface_name server_group
```

Where *acl\_name* is the name of the access list you created in [Step 2](#), *interface\_name* is the name of the interface as specified with the **nameif** command, and *server\_group* is the AAA server group you created in [Step 1](#).

**Note** You can alternatively use the **aaa authentication include** command (which identifies traffic within the command). However, you cannot use both methods in the same configuration. See the *Cisco ASA 5500 Series Command Reference* for more information.

- Step 4** (Optional) To enable the redirection method of authentication for HTTP or HTTPS connections, enter the following command:

```
hostname(config)# aaa authentication listener http[s] interface_name [port portnum]
redirect
```

where the *interface\_name* argument is the interface on which you want to enable listening ports.

The **port portnum** argument specifies the port number that the adaptive security appliance listens on; the defaults are 80 (HTTP) and 443 (HTTPS). You can use any port number and retain the same functionality, but be sure your direct authentication users know the port number; redirected traffic is sent to the correct port number automatically, but direct authenticators must specify the port number manually.

Enter this command separately for HTTP and for HTTPS.

- Step 5** (Optional) If you are using the local database for network access authentication and you want to limit the number of consecutive failed login attempts that the adaptive security appliance allows any given user account (with the exception of users with a privilege level of 15; this feature does not affect level 15 users), use the following command:

```
hostname(config)# aaa local authentication attempts max-fail number
```

Where *number* is between 1 and 16.

For example:

```
hostname(config)# aaa local authentication attempts max-fail 7
```

**Tip**

To clear the lockout status of a specific user or all users, use the **clear aaa local user lockout** command.

For example, the following commands authenticate all inside HTTP traffic and SMTP traffic:

```
hostname(config)# aaa-server AuthOutbound protocol tacacs+
hostname(config-aaa-server-group)# exit
hostname(config)# aaa-server AuthOutbound (inside) host 10.1.1.1
hostname(config-aaa-server-host)# key TACPlusUauthKey
hostname(config-aaa-server-host)# exit
hostname(config)# access-list MAIL_AUTH extended permit tcp any any eq smtp
hostname(config)# access-list MAIL_AUTH extended permit tcp any any eq www
hostname(config)# aaa authentication match MAIL_AUTH inside AuthOutbound
hostname(config)# aaa authentication listener http inside redirect
```

The following commands authenticate Telnet traffic from the outside interface to a particular server (209.165.201.5):

```
hostname(config)# aaa-server AuthInbound protocol tacacs+
hostname(config-aaa-server-group)# exit
hostname(config)# aaa-server AuthInbound (inside) host 10.1.1.1
hostname(config-aaa-server-host)# key TACPlusUauthKey
hostname(config-aaa-server-host)# exit
hostname(config)# access-list TELNET_AUTH extended permit tcp any host 209.165.201.5 eq telnet
hostname(config)# aaa authentication match TELNET_AUTH outside AuthInbound
```

## Enabling Secure Authentication of Web Clients

If you use HTTP authentication, by default the username and password are sent from the client to the adaptive security appliance in clear text; in addition, the username and password are sent on to the destination web server as well. The adaptive security appliance provides several methods of securing HTTP authentication:

- Enable the redirection method of authentication for HTTP—Use the **aaa authentication listener** command with the **redirect** keyword. This method prevents the authentication credentials from continuing to the destination server. See the [“Adaptive Security Appliance Authentication Prompts” section on page 35-2](#) for more information about the redirection method versus the basic method.
- Enable virtual HTTP—Use the **virtual http** command to let you authenticate separately with the adaptive security appliance and with the HTTP server. Even if the HTTP server does not need a second authentication, this command achieves the effect of stripping the basic authentication credentials from the HTTP GET request.
- Enable the exchange of usernames and passwords between a web client and the adaptive security appliance with HTTPS—Use the **aaa authentication secure-http-client** command to enable the exchange of usernames and passwords between a web client and the adaptive security appliance with HTTPS. This is the only method that protects credentials between the client and the adaptive security appliance, as well as between the adaptive security appliance and the destination server. You can use this method alone, or in conjunction with either of the other methods so you can maximize your security.

After enabling this feature, when a user requires authentication when using HTTP, the adaptive security appliance redirects the HTTP user to an HTTPS prompt. After you authenticate correctly, the adaptive security appliance redirects you to the original HTTP URL.

Secured web-client authentication has the following limitations:

- A maximum of 16 concurrent HTTPS authentication sessions are allowed. If all 16 HTTPS authentication processes are running, a new connection requiring authentication will not succeed.
- When **uauth timeout 0** is configured (the **uauth timeout** is set to 0), HTTPS authentication might not work. If a browser initiates multiple TCP connections to load a web page after HTTPS authentication, the first connection is let through, but the subsequent connections trigger authentication. As a result, users are continuously presented with an authentication page, even if the correct username and password are entered each time. To work around this, set the **uauth timeout** to 1 second with the **timeout uauth 0:0:1** command. However, this workaround opens a 1-second window of opportunity that might allow non-authenticated users to go through the firewall if they are coming from the same source IP address.
- Because HTTPS authentication occurs on the SSL port 443, users must not configure an **access-list** command statement to block traffic from the HTTP client to HTTP server on port 443. Furthermore, if static PAT is configured for web traffic on port 80, it must also be configured for the SSL port. In the following example, the first line configures static PAT for web traffic and the second line must be added to support the HTTPS authentication configuration.

```
object network obj-10.130.16.10-01
  host 10.130.16.10
  nat (inside,outside) static 10.132.16.200 service tcp 80 80
object network obj-10.130.16.10-02
  host 10.130.16.10
  nat (inside,outside) static 10.132.16.200 service tcp 443 443
```

## Authenticating Directly with the Adaptive Security Appliance

If you do not want to allow HTTP, HTTPS, Telnet, or FTP through the adaptive security appliance but want to authenticate other types of traffic, you can authenticate with the adaptive security appliance directly using HTTP, HTTPS, or Telnet.

This section includes the following topics:

- [Enabling Direct Authentication Using HTTP and HTTPS, page 35-6](#)
- [Enabling Direct Authentication Using Telnet, page 35-7](#)

### Enabling Direct Authentication Using HTTP and HTTPS

If you enabled the redirect method of HTTP and HTTPS authentication in the [“Enabling Network Access Authentication” section on page 35-4](#), then you also automatically enabled direct authentication.

If you want to continue to use basic HTTP authentication, but want to enable direct authentication for HTTP and HTTPS, then enter the following command:

```
hostname(config)# aaa authentication listener http[s] interface_name [port portnum]
```

where the *interface\_name* argument is the interface on which you want to enable direct authentication.

The **port** *portnum* argument specifies the port number that the adaptive security appliance listens on; the defaults are 80 (HTTP) and 443 (HTTPS).

Enter this command separately for HTTP and for HTTPS.

If the destination HTTP server requires authentication in addition to the adaptive security appliance, then the **virtual http** command lets you authenticate separately with the adaptive security appliance (via a AAA server) and with the HTTP server. Without virtual HTTP, the same username and password you used to authenticate with the adaptive security appliance is sent to the HTTP server; you are not prompted separately for the HTTP server username and password. Assuming the username and password is not the same for the AAA and HTTP servers, then the HTTP authentication fails.

This command redirects all HTTP connections that require AAA authentication to the virtual HTTP server on the adaptive security appliance. The adaptive security appliance prompts for the AAA server username and password. After the AAA server authenticates the user, the adaptive security appliance redirects the HTTP connection back to the original server, but it does not include the AAA server username and password. Because the username and password are not included in the HTTP packet, the HTTP server prompts the user separately for the HTTP server username and password.

For inbound users (from lower security to higher security), you must also include the virtual HTTP address as a destination interface in the access list applied to the source interface. Moreover, you must add a static NAT command for the virtual HTTP IP address, even if NAT is not required. An identity NAT command is typically used (where you translate the address to itself).

For outbound users, there is an explicit permit for traffic, but if you apply an access list to an inside interface, be sure to allow access to the virtual HTTP address. A static statement is not required.

**Note**

Do not set the **timeout uauth** command duration to 0 seconds when using the **virtual http** command, because this setting prevents HTTP connections to the real web server.

You can authenticate directly with the adaptive security appliance at the following URLs when you enable AAA for the interface:

```
http://interface_ip[:port]/netaccess/connstatus.html  
https://interface_ip[:port]/netaccess/connstatus.html
```

## Enabling Direct Authentication Using Telnet

Although you can configure network access authentication for any protocol or service (see the **aaa authentication match** or **aaa authentication include** command), you can authenticate directly with HTTP, Telnet, or FTP only. A user must first authenticate with one of these services before other traffic that requires authentication is allowed through. If you do not want to allow HTTP, Telnet, or FTP through the adaptive security appliance, but want to authenticate other types of traffic, you can configure virtual Telnet; the user Telnets to a given IP address configured on the adaptive security appliance, and the adaptive security appliance provides a Telnet prompt.

To configure a virtual Telnet server, enter the following command:

```
hostname(config)# virtual telnet ip_address
```

where the *ip\_address* argument sets the IP address for the virtual Telnet server. Make sure this address is an unused address that is routed to the adaptive security appliance.

You must configure authentication for Telnet access to the virtual Telnet address as well as the other services you want to authenticate using the **authentication match** or **aaa authentication include** command.

When an unauthenticated user connects to the virtual Telnet IP address, the user is challenged for a username and password, and then authenticated by the AAA server. Once authenticated, the user sees the message “Authentication Successful.” Then, the user can successfully access other services that require authentication.

For inbound users (from lower security to higher security), you must also include the virtual Telnet address as a destination interface in the access list applied to the source interface. Moreover, you must add a static NAT command for the virtual Telnet IP address, even if NAT is not required. An identity NAT command is typically used (where you translate the address to itself).

For outbound users, there is an explicit permit for traffic, but if you apply an access list to an inside interface, be sure to allow access to the virtual Telnet address. A static statement is not required.

To logout from the adaptive security appliance, reconnect to the virtual Telnet IP address; you are prompted to log out.

This example shows how to enable virtual Telnet along with AAA authentication for other services:

```
hostname(config)# virtual telnet 209.165.202.129
hostname(config)# access-list ACL-IN extended permit tcp any host 209.165.200.225 eq smtp
hostname(config)# access-list ACL-IN remark This is the SMTP server on the inside
hostname(config)# access-list ACL-IN extended permit tcp any host 209.165.202.129 eq
telnet
hostname(config)# access-list ACL-IN remark This is the virtual Telnet address
hostname(config)# access-group ACL-IN in interface outside
hostname(config)# network object obj-209.165.202.129-01
hostname(config-network-object)# host 209.165.202.129
hostname(config-network-object)# nat (inside,outside) static 209.165.202.129
hostname(config)# access-list AUTH extended permit tcp any host 209.165.200.225 eq smtp
hostname(config)# access-list AUTH remark This is the SMTP server on the inside
hostname(config)# access-list AUTH extended permit tcp any host 209.165.202.129 eq telnet
hostname(config)# access-list AUTH remark This is the virtual Telnet address
hostname(config)# aaa authentication match AUTH outside tacacs+
```

## Configuring Authorization for Network Access

After a user authenticates for a given connection, the adaptive security appliance can use authorization to further control traffic from the user.

This section includes the following topics:

- [Configuring TACACS+ Authorization, page 35-8](#)
- [Configuring RADIUS Authorization, page 35-10](#)

## Configuring TACACS+ Authorization

You can configure the adaptive security appliance to perform network access authorization with TACACS+. You identify the traffic to be authorized by specifying access lists that authorization rules must match. Alternatively, you can identify the traffic directly in authorization rules themselves.

**Tip**

Using access lists to identify traffic to be authorized can greatly reduced the number of authorization commands you must enter. This is because each authorization rule you enter can specify only one source and destination subnet and service, whereas an access list can include many entries.

Authentication and authorization statements are independent; however, any unauthenticated traffic matched by an authorization statement will be denied. For authorization to succeed, a user must first authenticate with the adaptive security appliance. Because a user at a given IP address only needs to authenticate one time for all rules and types, if the authentication session hasn't expired, authorization can occur even if the traffic is matched by an authentication statement.

After a user authenticates, the adaptive security appliance checks the authorization rules for matching traffic. If the traffic matches the authorization statement, the adaptive security appliance sends the username to the TACACS+ server. The TACACS+ server responds to the adaptive security appliance with a permit or a deny for that traffic, based on the user profile. The adaptive security appliance enforces the authorization rule in the response.

See the documentation for your TACACS+ server for information about configuring network access authorizations for a user.

To configure TACACS+ authorization, perform the following steps:

- Step 1** Enable authentication. For more information, see the [“Enabling Network Access Authentication” section on page 35-4](#). If you have already enabled authentication, continue to the next step.
- Step 2** Using the **access-list** command, create an access list that identifies the source addresses and destination addresses of traffic you want to authorize. For steps, see [Chapter 13, “Adding an Extended Access List.”](#)
- The **permit** ACEs mark matching traffic for authorization, while **deny** entries exclude matching traffic from authorization. The access list you use for authorization matching should contain rules that are equal to or a subset of the rules in the access list used for authentication matching.

**Note** If you have configured authentication and want to authorize all the traffic being authenticated, you can use the same access list you created for use with the **aaa authentication match** command.

- Step 3** To enable authorization, enter the following command:

```
hostname(config)# aaa authorization match acl_name interface_name server_group
```

where *acl\_name* is the name of the access list you created in [Step 2](#), *interface\_name* is the name of the interface as specified with the **nameif** command or by default, and *server\_group* is the AAA server group you created when you enabled authentication.

**Note** Alternatively, you can use the **aaa authorization include** command (which identifies traffic within the command) but you cannot use both methods in the same configuration. See the *Cisco ASA 5500 Series Command Reference* for more information.

The following commands authenticate and authorize inside Telnet traffic. Telnet traffic to servers other than 209.165.201.5 can be authenticated alone, but traffic to 209.165.201.5 requires authorization.

```
hostname(config)# access-list TELNET_AUTH extended permit tcp any any eq telnet
hostname(config)# access-list SERVER_AUTH extended permit tcp any host 209.165.201.5 eq telnet
hostname(config)# aaa-server AuthOutbound protocol tacacs+
hostname(config-aaa-server-group)# exit
hostname(config)# aaa-server AuthOutbound (inside) host 10.1.1.1
hostname(config-aaa-server-host)# key TACPlusUauthKey
hostname(config-aaa-server-host)# exit
```

```
hostname(config)# aaa authentication match TELNET_AUTH inside AuthOutbound
hostname(config)# aaa authorization match SERVER_AUTH inside AuthOutbound
```

## Configuring RADIUS Authorization

When authentication succeeds, the RADIUS protocol returns user authorizations in the access-accept message sent by a RADIUS server. For more information about configuring authentication, see the [“Configuring Authentication for Network Access” section on page 35-1](#).

When you configure the adaptive security appliance to authenticate users for network access, you are also implicitly enabling RADIUS authorizations; therefore, this section contains no information about configuring RADIUS authorization on the adaptive security appliance. It does provide information about how the adaptive security appliance handles access list information received from RADIUS servers.

You can configure a RADIUS server to download an access list to the adaptive security appliance or an access list name at the time of authentication. The user is authorized to do only what is permitted in the user-specific access list.

### Note

If you have used the **access-group** command to apply access lists to interfaces, be aware of the following effects of the **per-user-override** keyword on authorization by user-specific access lists:

- Without the **per-user-override** keyword, traffic for a user session must be permitted by both the interface access list and the user-specific access list.
- With the **per-user-override** keyword, the user-specific access list determines what is permitted.

For more information, see the **access-group** command entry in the *Cisco ASA 5500 Series Command Reference*.

This section includes the following topics:

- [Configuring a RADIUS Server to Send Downloadable Access Control Lists, page 35-10](#)
- [Configuring a RADIUS Server to Download Per-User Access Control List Names, page 35-14](#)

## Configuring a RADIUS Server to Send Downloadable Access Control Lists

This section describes how to configure Cisco Secure ACS or a third-party RADIUS server and includes the following topics:

- [About the Downloadable Access List Feature and Cisco Secure ACS, page 35-10](#)
- [Configuring Cisco Secure ACS for Downloadable Access Lists, page 35-12](#)
- [Configuring Any RADIUS Server for Downloadable Access Lists, page 35-13](#)
- [Converting Wildcard Netmask Expressions in Downloadable Access Lists, page 35-14](#)

### About the Downloadable Access List Feature and Cisco Secure ACS

Downloadable access lists is the most scalable means of using Cisco Secure ACS to provide the appropriate access lists for each user. It provides the following capabilities:

- Unlimited access list size—Downloadable access lists are sent using as many RADIUS packets as required to transport the full access list from Cisco Secure ACS to the adaptive security appliance.

- Simplified and centralized management of access lists—Downloadable access lists enable you to write a set of access lists once and apply it to many user or group profiles and distribute it to many adaptive security appliances.

This approach is most useful when you have very large access list sets that you want to apply to more than one Cisco Secure ACS user or group; however, its ability to simplify Cisco Secure ACS user and group management makes it useful for access lists of any size.

The adaptive security appliance receives downloadable access lists from Cisco Secure ACS using the following process:

1. The adaptive security appliance sends a RADIUS authentication request packet for the user session.
2. If Cisco Secure ACS successfully authenticates the user, Cisco Secure ACS returns a RADIUS access-accept message that contains the internal name of the applicable downloadable access list. The Cisco IOS cisco-av-pair RADIUS VSA (vendor 9, attribute 1) contains the following attribute-value pair to identify the downloadable access list set:

```
ACS:CiscoSecure-Defined-ACL=acl-set-name
```

where *acl-set-name* is the internal name of the downloadable access list, which is a combination of the name assigned to the access list by the Cisco Secure ACS administrator and the date and time that the access list was last modified.

3. The adaptive security appliance examines the name of the downloadable access list and determines if it has previously received the named downloadable access list.
  - If the adaptive security appliance has previously received the named downloadable access list, communication with Cisco Secure ACS is complete and the adaptive security appliance applies the access list to the user session. Because the name of the downloadable access list includes the date and time it was last modified, matching the name sent by Cisco Secure ACS to the name of an access list previously downloaded means that the adaptive security appliance has the most recent version of the downloadable access list.
  - If the adaptive security appliance has not previously received the named downloadable access list, it may have an out-of-date version of the access list or it may not have downloaded any version of the access list. In either case, the adaptive security appliance issues a RADIUS authentication request using the downloadable access list name as the username in the RADIUS request and a null password attribute. In a cisco-av-pair RADIUS VSA, the request also includes the following attribute-value pairs:

```
AAA:service=ip-admission  
AAA:event=acl-download
```

In addition, the adaptive security appliance signs the request with the Message-Authenticator attribute (IETF RADIUS attribute 80).

4. Upon receipt of a RADIUS authentication request that has a username attribute containing the name of a downloadable access list, Cisco Secure ACS authenticates the request by checking the Message-Authenticator attribute. If the Message-Authenticator attribute is missing or incorrect, Cisco Secure ACS ignores the request. The presence of the Message-Authenticator attribute prevents malicious use of a downloadable access list name to gain unauthorized network access. The Message-Authenticator attribute and its use are defined in RFC 2869, RADIUS Extensions, available at <http://www.ietf.org>.
5. If the access list required is less than approximately 4 KB in length, Cisco Secure ACS responds with an access-accept message containing the access list. The largest access list that can fit in a single access-accept message is slightly less than 4 KB because some of the message must be other required attributes.

Cisco Secure ACS sends the downloadable access list in a cisco-av-pair RADIUS VSA. The access list is formatted as a series of attribute-value pairs that each contain an ACE and are numbered serially:

```
ip:inacl#1=ACE-1
ip:inacl#2=ACE-2
.
.
.
ip:inacl#n=ACE-n
```

An example of an attribute-value pair follows:

```
ip:inacl#1=permit tcp 10.1.0.0 255.0.0.0 10.0.0.0 255.0.0.0
```

- If the access list required is more than approximately 4 KB in length, Cisco Secure ACS responds with an access-challenge message that contains a portion of the access list, formatted as described above, and an State attribute (IETF RADIUS attribute 24), which contains control data used by Cisco Secure ACS to track the progress of the download. Cisco Secure ACS fits as many complete attribute-value pairs into the cisco-av-pair RADIUS VSA as it can without exceeding the maximum RADIUS message size.

The adaptive security appliance stores the portion of the access list received and responds with another access-request message containing the same attributes as the first request for the downloadable access list plus a copy of the State attribute received in the access-challenge message.

This repeats until Cisco Secure ACS sends the last of the access list in an access-accept message.

## Configuring Cisco Secure ACS for Downloadable Access Lists

You can configure downloadable access lists on Cisco Secure ACS as a shared profile component and then assign the access list to a group or to an individual user.

The access list definition consists of one or more adaptive security appliance commands that are similar to the extended **access-list** command (see [Chapter 13, “Adding an Extended Access List,”](#)), except without the following prefix:

```
access-list acl_name extended
```

The following example is a downloadable access list definition on Cisco Secure ACS version 3.3:

```
+-----+
| Shared profile Components                                     |
|   |
|       Downloadable IP ACLs Content                         |
|   |
| Name:      acs_ten_acl                                     |
|   |
|       ACL Definitions                                       |
|   |
| permit tcp any host 10.0.0.254                             |
| permit udp any host 10.0.0.254                             |
| permit icmp any host 10.0.0.254                           |
| permit tcp any host 10.0.0.253                             |
| permit udp any host 10.0.0.253                             |
| permit icmp any host 10.0.0.253                           |
| permit tcp any host 10.0.0.252                             |
| permit udp any host 10.0.0.252                             |
| permit icmp any host 10.0.0.252                           |
| permit ip any any  |
+-----+
```

For more information about creating downloadable access lists and associating them with users, see the user guide for your version of Cisco Secure ACS.

On the adaptive security appliance, the downloaded access list has the following name:

```
#ACSACL#-ip-acl_name-number
```

The *acl\_name* argument is the name that is defined on Cisco Secure ACS (acs\_ten\_acl in the preceding example), and *number* is a unique version ID generated by Cisco Secure ACS.

The downloaded access list on the adaptive security appliance consists of the following lines:

```
access-list #ACSACL#-ip-asa-acsc_ten_acl-3b5385f7 permit tcp any host 10.0.0.254
access-list #ACSACL#-ip-asa-acsc_ten_acl-3b5385f7 permit udp any host 10.0.0.254
access-list #ACSACL#-ip-asa-acsc_ten_acl-3b5385f7 permit icmp any host 10.0.0.254
access-list #ACSACL#-ip-asa-acsc_ten_acl-3b5385f7 permit tcp any host 10.0.0.253
access-list #ACSACL#-ip-asa-acsc_ten_acl-3b5385f7 permit udp any host 10.0.0.253
access-list #ACSACL#-ip-asa-acsc_ten_acl-3b5385f7 permit icmp any host 10.0.0.253
access-list #ACSACL#-ip-asa-acsc_ten_acl-3b5385f7 permit tcp any host 10.0.0.252

access-list #ACSACL#-ip-asa-acsc_ten_acl-3b5385f7 permit icmp any host 10.0.0.252
access-list #ACSACL#-ip-asa-acsc_ten_acl-3b5385f7 permit ip any any
```

## Configuring Any RADIUS Server for Downloadable Access Lists

You can configure any RADIUS server that supports Cisco IOS RADIUS VSAs to send user-specific access lists to the adaptive security appliance in a Cisco IOS RADIUS cisco-av-pair VSA (vendor 9, attribute 1).

In the cisco-av-pair VSA, configure one or more ACEs that are similar to the **access-list extended** command (see [Chapter 13, “Adding an Extended Access List,”](#)), except that you replace the following command prefix:

```
access-list acl_name extended
```

with the following text:

```
ip:inacl#nnn=
```

The *nnn* argument is a number in the range from 0 to 999999999 that identifies the order of the command statement to be configured on the adaptive security appliance. If this parameter is omitted, the sequence value is 0, and the order of the ACEs inside the cisco-av-pair RADIUS VSA is used.

The following example is an access list definition as it should be configured for a cisco-av-pair VSA on a RADIUS server:

```
ip:inacl#1=permit tcp 10.1.0.0 255.0.0.0 10.0.0.0 255.0.0.0
ip:inacl#99=deny tcp any any
ip:inacl#2=permit udp 10.1.0.0 255.0.0.0 10.0.0.0 255.0.0.0
ip:inacl#100=deny udp any any
ip:inacl#3=permit icmp 10.1.0.0 255.0.0.0 10.0.0.0 255.0.0.0
```

For information about making unique per user the access lists that are sent in the cisco-av-pair attribute, see the documentation for your RADIUS server.

On the adaptive security appliance, the downloaded access list name has the following format:

```
AAA-user-username
```

The *username* argument is the name of the user that is being authenticated.

The downloaded access list on the adaptive security appliance consists of the following lines. Notice the order based on the numbers identified on the RADIUS server.

```

access-list AAA-user-bcham34-79AD4A08 permit tcp 10.1.0.0 255.0.0.0 10.0.0.0 255.0.0.0
access-list AAA-user-bcham34-79AD4A08 permit udp 10.1.0.0 255.0.0.0 10.0.0.0 255.0.0.0
access-list AAA-user-bcham34-79AD4A08 permit icmp 10.1.0.0 255.0.0.0 10.0.0.0 255.0.0.0
access-list AAA-user-bcham34-79AD4A08 deny tcp any any
access-list AAA-user-bcham34-79AD4A08 deny udp any any

```

Downloaded access lists have two spaces between the word “access-list” and the name. These spaces serve to differentiate a downloaded access list from a local access list. In this example, “79AD4A08” is a hash value generated by the adaptive security appliance to help determine when access list definitions have changed on the RADIUS server.

## Converting Wildcard Netmask Expressions in Downloadable Access Lists

If a RADIUS server provides downloadable access lists to Cisco VPN 3000 series concentrators as well as to the adaptive security appliance, you may need the adaptive security appliance to convert wildcard netmask expressions to standard netmask expressions. This is because Cisco VPN 3000 series concentrators support wildcard netmask expressions but the adaptive security appliance only supports standard netmask expressions. Configuring the adaptive security appliance to convert wildcard netmask expressions helps minimize the effects of these differences upon how you configure downloadable access lists on your RADIUS servers. Translation of wildcard netmask expressions means that downloadable access lists written for Cisco VPN 3000 series concentrators can be used by the adaptive security appliance without altering the configuration of the downloadable access lists on the RADIUS server.

You configure access list netmask conversion on a per-server basis, using the **acl-netmask-convert** command, available in the **aaa-server** configuration mode. For more information about configuring a RADIUS server, see [“Identifying AAA Server Groups and Servers” section on page 33-11](#). For more information about the **acl-netmask-convert** command, see the *Cisco ASA 5500 Series Command Reference*.

## Configuring a RADIUS Server to Download Per-User Access Control List Names

To download a name for an access list that you already created on the adaptive security appliance from the RADIUS server when a user authenticates, configure the IETF RADIUS filter-id attribute (attribute number 11) as follows:

```
filter-id=acl_name
```

### Note

In Cisco Secure ACS, the value for filter-id attributes are specified in boxes in the HTML interface, omitting **filter-id=** and entering only *acl\_name*.

For information about making unique per user the filter-id attribute value, see the documentation for your RADIUS server.

See [Chapter 13, “Adding an Extended Access List,”](#) to create an access list on the adaptive security appliance.

# Configuring Accounting for Network Access

The adaptive security appliance can send accounting information to a RADIUS or TACACS+ server about any TCP or UDP traffic that passes through the adaptive security appliance. If that traffic is also authenticated, then the AAA server can maintain accounting information by username. If the traffic is

not authenticated, the AAA server can maintain accounting information by IP address. Accounting information includes when sessions start and stop, username, the number of bytes that pass through the adaptive security appliance for the session, the service used, and the duration of each session.

To configure accounting, perform the following steps:

- Step 1** If you want the adaptive security appliance to provide accounting data per user, you must enable authentication. For more information, see the [“Enabling Network Access Authentication” section on page 35-4](#). If you want the adaptive security appliance to provide accounting data per IP address, enabling authentication is not necessary and you can continue to the next step.
- Step 2** Using the **access-list** command, create an access list that identifies the source addresses and destination addresses of traffic you want accounted. For steps, see [Chapter 13, “Adding an Extended Access List.”](#) The **permit** ACEs mark matching traffic for authorization, while **deny** entries exclude matching traffic from authorization.

**Note** If you have configured authentication and want accounting data for all the traffic being authenticated, you can use the same access list you created for use with the **aaa authentication match** command.

- Step 3** To enable accounting, enter the following command:

```
hostname(config)# aaa accounting match acl_name interface_name server_group
```

where the *acl\_name* argument is the access list name set in the **access-list** command.

The *interface\_name* argument is the interface name set in the **nameif** command.

The *server\_group* argument is the server group name set in the **aaa-server** command.

**Note** Alternatively, you can use the **aaa accounting include** command (which identifies traffic within the command) but you cannot use both methods in the same configuration. See the *Cisco ASA 5500 Series Command Reference* for more information.

The following commands authenticate, authorize, and account for inside Telnet traffic. Telnet traffic to servers other than 209.165.201.5 can be authenticated alone, but traffic to 209.165.201.5 requires authorization and accounting.

```
hostname(config)# aaa-server AuthOutbound protocol tacacs+
hostname(config-aaa-server-group)# exit
hostname(config)# aaa-server AuthOutbound (inside) host 10.1.1.1
hostname(config-aaa-server-host)# key TACPlusUauthKey
hostname(config-aaa-server-host)# exit
hostname(config)# access-list TELNET_AUTH extended permit tcp any any eq telnet
hostname(config)# access-list SERVER_AUTH extended permit tcp any host 209.165.201.5 eq telnet
hostname(config)# aaa authentication match TELNET_AUTH inside AuthOutbound
hostname(config)# aaa authorization match SERVER_AUTH inside AuthOutbound
hostname(config)# aaa accounting match SERVER_AUTH inside AuthOutbound
```

# Using MAC Addresses to Exempt Traffic from Authentication and Authorization

The adaptive security appliance can exempt from authentication and authorization any traffic from specific MAC addresses. For example, if the adaptive security appliance authenticates TCP traffic originating on a particular network but you want to allow unauthenticated TCP connections from a specific server, you would use a MAC exempt rule to exempt from authentication and authorization any traffic from the server specified by the rule.

This feature is particularly useful to exempt devices such as IP phones that cannot respond to authentication prompts.

To use MAC addresses to exempt traffic from authentication and authorization, perform the following steps:

---

**Step 1** To configure a MAC list, enter the following command:

```
hostname(config)# mac-list id {deny | permit} mac macmask
```

Where the *id* argument is the hexadecimal number that you assign to the MAC list. To group a set of MAC addresses, enter the **mac-list** command as many times as needed with the same ID value. Because you can only use one MAC list for AAA exemption, be sure that your MAC list includes all the MAC addresses you want to exempt. You can create multiple MAC lists, but you can only use one at a time.

The order of entries matters, because the packet uses the first entry it matches, as opposed to a best match scenario. If you have a permit entry, and you want to deny an address that is allowed by the permit entry, be sure to enter the deny entry before the permit entry.

The *mac* argument specifies the source MAC address in 12-digit hexadecimal form; that is, nnnn.nnnn.nnnn.

The *macmask* argument specifies the portion of the MAC address that should be used for matching. For example, ffff.ffff.ffff matches the MAC address exactly. ffff.ffff.0000 matches only the first 8 digits.

**Step 2** To exempt traffic for the MAC addresses specified in a particular MAC list, enter the following command:

```
hostname(config)# aaa mac-exempt match id
```

Where *id* is the string identifying the MAC list containing the MAC addresses whose traffic is to be exempt from authentication and authorization. You can only enter one instance of the **aaa mac-exempt** command.

---

The following example bypasses authentication for a single MAC address:

```
hostname(config)# mac-list abc permit 00a0.c95d.0282 ffff.ffff.ffff
hostname(config)# aaa mac-exempt match abc
```

The following entry bypasses authentication for all Cisco IP Phones, which have the hardware ID 0003.E3:

```
hostname(config)# mac-list acd permit 0003.E300.0000 FFFF.FF00.0000
hostname(config)# aaa mac-exempt match acd
```

The following example bypasses authentication for a group of MAC addresses except for 00a0.c95d.02b2. Enter the deny statement before the permit statement, because 00a0.c95d.02b2 matches the permit statement as well, and if it is first, the deny statement will never be matched.

```
hostname(config)# mac-list 1 deny 00a0.c95d.0282 ffff.ffff.ffff  
hostname(config)# mac-list 1 permit 00a0.c95d.0000 ffff.ffff.0000  
hostname(config)# aaa mac-exempt match 1
```

-

# CHAPTER 36

## Configuring Filtering Services

---

This chapter describes how to use filtering services to provide greater control over traffic passing through the adaptive security appliance and includes the following sections:

- [Information About Web Traffic Filtering, page 36-1](#)
- [Configuring ActiveX Filtering, page 36-2](#)
- [Configuring Java Applet Filtering, page 36-4](#)
- [Filtering URLs and FTP Requests with an External Server, page 36-6](#)
- [Monitoring Filtering Statistics, page 36-14](#)

## Information About Web Traffic Filtering

You can use web traffic filtering in two distinct ways:

- Filtering ActiveX objects or Java applets
- Filtering with an external filtering server

Instead of blocking access altogether, you can remove specific undesirable objects from web traffic, such as ActiveX objects or Java applets, that may pose a security threat in certain situations.

You can use web traffic filtering to direct specific traffic to an external filtering server, such as Secure Computing SmartFilter (formerly N2H2) or the Websense filtering server. You can enable long URL, HTTPS, and FTP filtering using either Websense or Secure Computing SmartFilter for web traffic filtering. Filtering servers can block traffic to specific sites or types of sites, as specified by the security policy.

### Note

---

URL caching will only work if the version of the URL server software from the URL server vendor supports it.

---

Because web traffic filtering is CPU-intensive, using an external filtering server ensures that the throughput of other traffic is not affected. However, depending on the speed of your network and the capacity of your web traffic filtering server, the time required for the initial connection may be noticeably slower when filtering traffic with an external filtering server.

# Configuring ActiveX Filtering

This section includes the following topics:

- [Information About ActiveX Filtering, page 36-2](#)
- [Licensing Requirements for ActiveX Filtering, page 36-2](#)
- [Guidelines and Limitations for ActiveX Filtering, page 36-3](#)
- [Configuring ActiveX Filtering, page 36-3](#)
- [Configuration Examples for ActiveX Filtering, page 36-3](#)
- [Feature History for ActiveX Filtering, page 36-4](#)

## Information About ActiveX Filtering

ActiveX objects may pose security risks because they can contain code intended to attack hosts and servers on a protected network. You can disable ActiveX objects with ActiveX filtering.

ActiveX controls, formerly known as OLE or OCX controls, are components that you can insert in a web page or another application. These controls include custom forms, calendars, or any of the extensive third-party forms for gathering or displaying information. As a technology, ActiveX creates many potential problems for network clients including causing workstations to fail, introducing network security problems, or being used to attack servers.

The **filteractivex** command blocks the HTML **object** commands by commenting them out within the HTML web page. ActiveX filtering of HTML files is performed by selectively replacing the <APPLET> and </APPLET>, and <OBJECT CLASSID> and </OBJECT> tags with comments. Filtering of nested tags is supported by converting top-level tags to comments.

### Caution

The **filteractivex** command also blocks any Java applets, image files, or multimedia objects that are embedded in object tags.

If the <object> or </object> HTML tags split across network packets or if the code in the tags is longer than the number of bytes in the MTU, the adaptive security appliance cannot block the tag.

ActiveX blocking does not occur when users access an IP address referenced by the **alias** command or for clientless SSL VPN traffic.

## Licensing Requirements for ActiveX Filtering

The following table shows the licensing requirements for this feature:

**Table 36-1**      *Licensing Requirements*

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Guidelines and Limitations for ActiveX Filtering

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

### IPv6 Guidelines

Supports IPv6.

## Configuring ActiveX Filtering

To remove ActiveX objects in HTTP traffic that is passing through the adaptive security appliance, enter the following command:

| Command                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>filteractivex</b> <i>port[-port] local_ip local_mask foreign_ip foreign_mask</i><br><br><b>Example:</b><br>hostname# <b>filteractivex 80 0 0 0 0</b> | Removes ActiveX objects. To use this command, replace <i>port[-port]</i> with the TCP port to which filtering is applied. Typically, this is port 80, but other values are accepted. The <b>http</b> or <b>url</b> literal can be used for port 80. You can specify a range of ports by using a hyphen between the starting port number and the ending port number. The local IP address and mask identify one or more internal hosts that are the source of the traffic to be filtered. The foreign address and mask specify the external destination of the traffic to be filtered. |

## Configuration Examples for ActiveX Filtering

You can set either address to **0.0.0.0** (or in shortened form, **0**) to specify all hosts. You can use **0.0.0.0** for either mask (or in shortened form, **0**) to specify all masks. This command specifies that the ActiveX object blocking applies to HTTP traffic on port 80 from any local host and for connections to any foreign host.

The following example shows how to configure ActiveX filtering to block all outbound connections:

```
hostname(config)# filteractivex 80 0 0 0 0
```

The following example shows how to remove ActiveX filtering:

```
hostname(config)# no filteractivex 80 0 0 0 0
```

## Feature History for ActiveX Filtering

Table 36-2 lists the release history for ActiveX Filtering. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

**Table 36-2**      *Feature History for ActiveX Filtering*

| Feature Name      | Platform Releases | Feature Information                                                                                                                      |
|-------------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| ActiveX filtering | 7.0(1)            | Filters specific undesirable objects from HTTP traffic, such as ActiveX objects, which may pose a security threat in certain situations. |

## Configuring Java Applet Filtering

This section includes the following topics:

- [Information About Java Applet Filtering, page 36-4](#)
- [Licensing Requirements for Java Applet Filtering, page 36-4](#)
- [Guidelines and Limitations for Java Applet Filtering, page 36-5](#)
- [Configuring Java Applet Filtering, page 36-5](#)
- [Configuration Examples for Java Applet Filtering, page 36-5](#)
- [Feature History for Java Applet Filtering, page 36-6](#)

## Information About Java Applet Filtering

Java applets may pose security risks because they can contain code intended to attack hosts and servers on a protected network. You can remove Java applets with the **filter java** command.

### Note

Use the **filter activex** command to remove Java applets that are embedded in <object> tags.

The **filter java** command filters out Java applets that return to the adaptive security appliance from an outbound connection. You still receive the HTML page, but the web page source for the applet is commented out so that the applet cannot execute. The **filter java** command does not filter clientless SSL VPN traffic.

## Licensing Requirements for Java Applet Filtering

The following table shows the licensing requirements for Java applet filtering:

**Table 36-3**      *Licensing Requirements*

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Guidelines and Limitations for Java Applet Filtering

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

### IPv6 Guidelines

Supports IPv6.

## Configuring Java Applet Filtering

To apply filtering to remove Java applets from HTTP traffic passing through the adaptive security appliance, enter the following command:

| Command                                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre><b>filter java</b> <i>port[-port] local_ip</i> <i>local_mask foreign_ip foreign_mask</i></pre> <p><b>Example:</b></p> <pre>hostname# filter java 80 0 0 0 0</pre> | <p>Removes Java applets in HTTP traffic passing through the adaptive security appliance.</p> <p>To use this command, replace <i>port[-port]</i> with the TCP port to which filtering is applied. Typically, this is port 80, but other values are accepted. The <b>http</b> or <b>url</b> literal can be used for port 80. You can specify a range of ports by using a hyphen between the starting port number and the ending port number.</p> <p>The local IP address and mask identify one or more internal hosts that are the source of the traffic to be filtered. The foreign address and mask specify the external destination of the traffic to be filtered.</p> <p>You can set either address to <b>0.0.0.0</b> (or in shortened form, <b>0</b>) to specify all hosts. You can use <b>0.0.0.0</b> for either mask (or in shortened form, <b>0</b>) to specify all hosts.</p> <p>You can set either address to <b>0.0.0.0</b> (or in shortened form, <b>0</b>) to specify all hosts. You can use <b>0.0.0.0</b> for either mask (or in shortened form, <b>0</b>) to specify all hosts.</p> |

## Configuration Examples for Java Applet Filtering

The following example specifies that Java applets are blocked on all outbound connections:

```
hostname(config)# filter java 80 0 0 0 0
```

This command specifies that the Java applet blocking applies to web traffic on port 80 from any local host and for connections to any foreign host.

The following example blocks downloading of Java applets to a host on a protected network:

```
hostname(config)# filter java http 192.168.3.3 255.255.255.255 0 0
```

This command prevents host 192.168.3.3 from downloading Java applets.

The following example removes the configuration for downloading Java applets to a host on a protected network:

```
hostname(config)# no filter java http 192.168.3.3 255.255.255.255 0 0
```

This command allows host 192.168.3.3 to download Java applets.

## Feature History for Java Applet Filtering

Table 36-2 lists the release history for Java applet filtering. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

**Table 36-4** Feature History for Java Applet Filtering

| Feature Name          | Platform Releases | Feature Information                                                                                                                   |
|-----------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| Java applet filtering | 7.0(1)            | Filters specific undesirable objects from HTTP traffic, such as Java applets, which may pose a security threat in certain situations. |

## Filtering URLs and FTP Requests with an External Server

This section describes how to filter URLs and FTP requests with an external server and includes the following topics:

- [Information About URL Filtering, page 36-6](#)
- [Licensing Requirements for URL Filtering, page 36-7](#)
- [Guidelines and Limitations for URL Filtering, page 36-7](#)
- [Identifying the Filtering Server, page 36-7](#)
- [Configuring Additional URL Filtering Settings, page 36-9](#)
- [Feature History for URL Filtering, page 36-16](#)

## Information About URL Filtering

You can apply filtering to connection requests originating from a more secure network to a less secure network. Although you can use ACLs to prevent outbound access to specific content servers, managing usage this way is difficult because of the size and dynamic nature of the Internet. You can simplify configuration and improve adaptive security appliance performance by using a separate server running one of the following Internet filtering products:

- Websense Enterprise for filtering HTTP, HTTPS, and FTP.
- Secure Computing SmartFilter (formerly N2H2) for filtering HTTP, HTTPS, FTP, and long URL filtering.

### Note

URL caching will only work if the version of the URL server software from the URL server vendor supports it.

Although adaptive security appliance performance is less affected when using an external server, you may notice longer access times to websites or FTP servers when the filtering server is remote from the adaptive security appliance.

When filtering is enabled and a request for content is directed through the adaptive security appliance, the request is sent to the content server and to the filtering server at the same time. If the filtering server allows the connection, the adaptive security appliance forwards the response from the content server to the originating client. If the filtering server denies the connection, the adaptive security appliance drops the response and sends a message or return code indicating that the connection was not successful.

If user authentication is enabled on the adaptive security appliance, then the adaptive security appliance also sends the username to the filtering server. The filtering server can use user-specific filtering settings or provide enhanced reporting about usage.

## Licensing Requirements for URL Filtering

The following table shows the licensing requirements for URL filtering:

**Table 36-5**      *Licensing Requirements*

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Guidelines and Limitations for URL Filtering

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

### IPv6 Guidelines

Supports IPv6.

## Identifying the Filtering Server

You can identify up to four filtering servers per context. The adaptive security appliance uses the servers in order until a server responds. In single mode, a maximum of 16 of the same type of filtering servers are allowed. You can only configure a single type of server (Websense or Secure Computing SmartFilter) in your configuration.

### Note

You must add the filtering server before you can configure filtering for HTTP or HTTPS with the **filter** command. If you remove the filtering servers from the configuration, then all **filter** commands are also removed.

To specify the external filtering server, enter the following command:

| Command                                                                                                                                                                                                                                                                                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Choose from the following options:                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <p>For Websense:</p> <pre>hostname(config)# url-server (if_name) host local_ip [timeout seconds] [protocol TCP   UDP version [1 4] [connections num_conns]]</pre> <p><b>Example:</b></p> <pre>hostname(config)# url-server (perimeter) host 10.0.1.1 protocol TCP version 4</pre>                                                                                                                             | <p>Identifies the address of the filtering server. <i>if_name</i> is the name of the adaptive security appliance interface connected to the filtering server (the default is inside). For the <b>vendor</b> {<i>secure-computing</i>   <i>n2h2</i>} option, use <i>secure-computing</i> as the vendor string; however, <i>n2h2</i> is acceptable for backward compatibility. When the configuration entries are generated, <i>secure-computing</i> is saved as the vendor string. The <b>host local_ip</b> option is the IP address of the URL filtering server. The <b>port number</b> option is the Secure Computing SmartFilter server port number of the filtering server; the adaptive security appliance also listens for UDP replies on this port.</p> <p><b>Note</b> The default port is 4005, which is used by the Secure Computing SmartFilter server to communicate to the adaptive security appliance via TCP or UDP. For information about changing the default port, see the <i>Filtering by N2H2 Administrator's Guide</i>.</p> <p>The <b>timeout seconds</b> option is the number of seconds that the adaptive security appliance should keep trying to connect to the filtering server. The <b>connections number</b> option is the number of tries to make a connection between the host and server.</p> <p>The example identifies a Websense filtering server with the IP address 10.0.1.1 on a perimeter interface of the adaptive security appliance. Version 4, which is enabled in this example, is recommended by Websense because it supports caching.</p> |
| <p>For Secure Computing SmartFilter (formerly N2H2):</p> <pre>hostname(config)# url-server (if_name) vendor {secure-computing   n2h2} host local_ip [port number] [timeout seconds] [protocol {TCP [connections number]}   UDP]</pre> <p><b>Example:</b></p> <pre>hostname(config)# url-server (perimeter) vendor n2h2 host 10.0.1.1 hostname(config)# url-server (perimeter) vendor n2h2 host 10.0.1.2</pre> | <p>The example identifies redundant Secure Computing SmartFilter servers that are both on a perimeter interface of the adaptive security appliance.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Configuring Additional URL Filtering Settings

After you have accessed a website, the filtering server can allow the adaptive security appliance to cache the server address for a certain period of time, as long as each website hosted at the address is in a category that is permitted at all times. When you access the server again, or if another user accesses the server, the adaptive security appliance does not need to consult the filtering server again to obtain the server address.

**Note** Requests for cached IP addresses are not passed to the filtering server and are not logged. As a result, this activity does not appear in any reports.

This section describes how to configure additional URL filtering settings and includes the following topics:

- [Buffering the Content Server Response, page 36-9](#)
- [Caching Server Addresses, page 36-10](#)
- [Filtering HTTP URLs, page 36-10](#)
- [Filtering HTTPS URLs, page 36-12](#)
- [Filtering FTP Requests, page 36-13](#)

### Buffering the Content Server Response

When you issue a request to connect to a content server, the adaptive security appliance sends the request to the content server and to the filtering server at the same time. If the filtering server does not respond before the content server, the server response is dropped. This behavior delays the web server response for the web client, because the web client must reissue the request.

By enabling the HTTP response buffer, replies from web content servers are buffered, and the responses are forwarded to the requesting client if the filtering server allows the connection. This behavior prevents the delay that might otherwise occur.

To configure buffering for responses to HTTP or FTP requests, enter the following command:

|        | Command                                                               | Purpose                                                                                                                                                                                                                                                                                                        |
|--------|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>url-block block block-buffer-limit</code>                       | Enables buffering of responses for HTTP or FTP requests that are pending a response from the filtering server.                                                                                                                                                                                                 |
|        | <b>Example:</b><br><code>hostname# url-block 3000</code>              | Replaces <i>block-buffer</i> with the maximum number of HTTP responses that can be buffered while awaiting responses from the URL server.<br><br><br><b>Note</b> Buffering of URLs longer than 3072 bytes is not supported. |
| Step 2 | <code>url-block mempool-size memory-pool-size</code>                  | Configures the maximum memory available for buffering pending URLs (and for buffering long URLs).                                                                                                                                                                                                              |
|        | <b>Example:</b><br><code>hostname# url-block mempool-size 5000</code> | Replaces <i>memory-pool-size</i> with a value from 2 to 10240 for a maximum memory allocation of 2 KB to 10 MB.                                                                                                                                                                                                |

## Caching Server Addresses

After you access a website, the filtering server can allow the adaptive security appliance to cache the server address for a certain period of time, as long as each website hosted at the address is in a category that is permitted at all times. When you access the server again, or if another user accesses the server, the adaptive security appliance does not need to consult the filtering server again.

### Note

Requests for cached IP addresses are not passed to the filtering server and are not logged. As a result, this activity does not appear in any reports. You can accumulate Websense run logs before using the **url-cache** command.

To improve throughput, enter the following command:

| Command                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>url-cache <i>dst</i>   <i>src_dst</i> <i>size</i></code>          | Replaces <i>size</i> with a value for the cache size within the range from 1 to 128 (KB).                                                                                                                                                                                                                                                                                                                                                        |
| <b>Example:</b><br><code>hostname## url-cache <i>src_dst</i> 100</code> | <p>Uses the <b>dst</b> keyword to cache entries based on the URL destination address. Choose this option if all users share the same URL filtering policy on the Websense server.</p> <p>Uses the <b>src_dst</b> keyword to cache entries based on both the source address initiating the URL request as well as the URL destination address. Choose this option if users do not share the same URL filtering policy on the Websense server.</p> |

## Filtering HTTP URLs

This section describes how to configure HTTP filtering with an external filtering server and includes the following topics:

- [Enabling HTTP Filtering, page 36-11](#)
- [Enabling Filtering of Long HTTP URLs, page 36-11](#)
- [Truncating Long HTTP URLs, page 36-12](#)
- [Exempting Traffic from Filtering, page 36-12](#)

## Enabling HTTP Filtering

You must identify and enable the URL filtering server before enabling HTTP filtering. When the filtering server approves an HTTP connection request, the adaptive security appliance allows the reply from the web server to reach the originating client. If the filtering server denies the request, the adaptive security appliance redirects you to a block page, indicating that access was denied.

To enable HTTP filtering, enter the following command:

| Command                                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>filter url</b> [ <b>http</b>   <i>port[-port]</i> <i>local_ip</i> <i>local_mask</i> <i>foreign_ip</i> <i>foreign_mask</i> ] [ <b>allow</b> ] [ <b>proxy-block</b> ]<br><br><b>Example:</b><br>hostname# filter url http allow proxy-block | Replaces <i>port[-port]</i> with one or more port numbers if a different port than the default port for HTTP (80) is used.<br><br>Replaces <i>local_ip</i> and <i>local_mask</i> with the IP address and subnet mask of a user or subnetwork making requests.<br><br>Replaces <i>foreign_ip</i> and <i>foreign_mask</i> with the IP address and subnet mask of a server or subnetwork responding to requests.<br><br>The <b>allow</b> option causes the adaptive security appliance to forward HTTP traffic without filtering when the primary filtering server is unavailable. Use the <b>proxy-block</b> command to drop all requests to proxy servers. |

## Enabling Filtering of Long HTTP URLs

By default, the adaptive security appliance considers an HTTP URL to be a long URL if it is greater than 1159 characters. You can increase the maximum length allowed.

To configure the maximum size of a single URL, enter the following command:

| Command                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>url-block url-size</b> <i>long-url-size</i><br><br><b>Example:</b><br>hostname# url-block url-size 3 | Replaces the <i>long-url-size</i> with the maximum size in KB for each long URL being buffered. For Websense servers, this is a value from 2 to 4 for a maximum URL size from 2 KB to 4 KB; for Secure Computing SmartFilter servers, this is a value between 2 and 3 for a maximum URL size from 2 KB to 3 KB. The default value is 2. |

## Truncating Long HTTP URLs

By default, if a URL exceeds the maximum permitted size, then it is dropped. To avoid this occurrence, truncate a long URL by entering the following command:

| Command                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>filter url</b> [ <b>longurl-truncate</b>   <b>longurl-deny</b>   <b>cgi-truncate</b> ]<br><br><b>Example:</b><br>hostname# filter url longurl-truncate | <p>The <b>longurl-truncate</b> option causes the adaptive security appliance to send only the hostname or IP address portion of the URL for evaluation to the filtering server when the URL is longer than the maximum length permitted. Use the <b>longurl-deny</b> option to deny outbound URL traffic if the URL is longer than the maximum permitted.</p> <p>Use the <b>cgi-truncate</b> option to truncate CGI URLs to include only the CGI script location and the script name without any parameters. Many long HTTP requests are CGI requests. If the parameters list is very long, waiting and sending the complete CGI request, including the parameter list, can use up memory resources and affect adaptive security appliance performance.</p> |

## Exempting Traffic from Filtering

To exempt traffic from filtering, enter following command:

| Command                                                                                                                                                                                                                       | Purpose                                                                                                                                                                           |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>filter url except</b> <i>source_ip source_mask</i><br><i>dest_ip dest_mask</i><br><br><b>Example:</b><br>hostname(config)# filter url http 0 0 0 0<br>hostname(config)# filter url except<br>10.0.2.54 255.255.255.255 0 0 | <p>Exempts specific traffic from filtering.</p> <p>The example shows how to cause all HTTP requests to be forwarded to the filtering server, except for those from 10.0.2.54.</p> |

## Filtering HTTPS URLs

You must identify and enable the URL filtering server before enabling HTTPS filtering.

### Note

Websense and Secure Computing Smartfilter currently support HTTPS; older versions of the Secure Computing SmartFilter (formerly N2H2) do not support HTTPS filtering.

Because HTTPS content is encrypted, the adaptive security appliance sends the URL lookup without directory and filename information. When the filtering server approves an HTTPS connection request, the adaptive security appliance allows the completion of SSL connection negotiation and allows the reply from the web server to reach the originating client. If the filtering server denies the request, the adaptive security appliance prevents the completion of SSL connection negotiation. The browser displays an error message, such as “The Page or the content cannot be displayed.”

### Note

The adaptive security appliance does not provide an authentication prompt for HTTPS, so you must authenticate with the adaptive security appliance using HTTP or FTP before accessing HTTPS servers.

To enable HTTPS filtering, enter the following command:

| Command                                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>filter https port[-port] localIP local_mask foreign_IP foreign_mask [allow]</pre> <p><b>Example:</b></p> <pre>hostname# filter https 443 0 0 0 0 0 0 0 0 allow</pre> | <p>Enables HTTPS filtering.</p> <p>Replaces <i>port[-port]</i> with a range of port numbers if a different port than the default port for HTTPS (443) is used.</p> <p>Replaces <i>local_ip</i> and <i>local_mask</i> with the IP address and subnet mask of a user or subnetwork making requests.</p> <p>Replaces <i>foreign_ip</i> and <i>foreign_mask</i> with the IP address and subnet mask of a server or subnetwork responding to requests.</p> <p>The <b>allow</b> option causes the adaptive security appliance to forward HTTPS traffic without filtering when the primary filtering server is unavailable.</p> |

## Filtering FTP Requests

You must identify and enable the URL filtering server before enabling FTP filtering.

### Note

Websense and Secure Computing Smartfilter currently support FTP; older versions of Secure Computing SmartFilter (formerly known as N2H2) did not support FTP filtering.

When the filtering server approves an FTP connection request, the adaptive security appliance allows the successful FTP return code to reach the originating client. For example, a successful return code is “250: CWD command successful.” If the filtering server denies the request, the FTP return code is changed to show that the connection was denied. For example, the adaptive security appliance changes code 250 to “550 Requested file is prohibited by URL filtering policy.”

To enable FTP filtering, enter the following command:

| Command                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>filter ftp port[-port] localIP local_mask foreign_IP foreign_mask [allow] [interact-block]</pre> <p><b>Example:</b></p> <pre>hostname# filter ftp 21 0 0 0 0 0 0 0 0 allow</pre> | <p>Enables FTP filtering.</p> <p>Replaces <i>port[-port]</i> with a range of port numbers if a different port than the default port for FTP (21) is used.</p> <p>Replaces <i>local_ip</i> and <i>local_mask</i> with the IP address and subnet mask of a user or subnetwork making requests.</p> <p>Replaces <i>foreign_ip</i> and <i>foreign_mask</i> with the IP address and subnet mask of a server or subnetwork responding to requests.</p> <p>The <b>allow</b> option causes the adaptive security appliance to forward HTTPS traffic without filtering when the primary filtering server is unavailable.</p> <p>Use the <b>interact-block</b> option to prevent interactive FTP sessions that do not provide the entire directory path. An interactive FTP client allows you to change directories without typing the entire path. For example, you might enter <b>cd ./files</b> instead of <b>cd /public/files</b>.</p> |

# Monitoring Filtering Statistics

To monitor filtering statistics, enter one of the following commands:

| Command                                | Purpose                                                                                                                                           |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>show url-server</b>                 | Shows information about the URL filtering server.                                                                                                 |
| <b>show url-server statistics</b>      | Shows URL filtering statistics.                                                                                                                   |
| <b>show url-block</b>                  | Shows the number of packets held in the url-block buffer and the number (if any) dropped because of exceeding the buffer limit or retransmission. |
| <b>show url-block block statistics</b> | Shows the URL block statistics.                                                                                                                   |
| <b>show url-cache stats</b>            | Shows the URL cache statistics.                                                                                                                   |
| <b>show perfmon</b>                    | Shows URL filtering performance statistics, along with other performance statistics.                                                              |
| <b>show filter</b>                     | Shows the filtering configuration.                                                                                                                |

## Examples

The following is sample output from the **show url-server** command:

```
hostname# show url-server
url-server (outside) vendor n2h2 host 128.107.254.202 port 4005 timeout 5 protocol TCP
```

The following is sample output from the **show url-server statistics** command:

```
hostname# show url-server statistics

Global Statistics:
-----
URLs total/allowed/denied      13/3/10
URLs allowed by cache/server    0/3
URLs denied by cache/server     0/10
HTTPSs total/allowed/denied    138/137/1
HTTPSs allowed by cache/server  0/137
HTTPSs denied by cache/server   0/1
FTPs total/allowed/denied      0/0/0
FTPs allowed by cache/server    0/0
FTPs denied by cache/server     0/0
Requests dropped                0
Server timeouts/retries        0/0
Processed rate average 60s/300s 0/0 requests/second
Denied rate average 60s/300s   0/0 requests/second
Dropped rate average 60s/300s  0/0 requests/second

Server Statistics:
-----
10.125.76.20                  UP
  Vendor                      websense
  Port                        15868
  Requests total/allowed/denied 151/140/11
  Server timeouts/retries      0/0
  Responses received            151
  Response time average 60s/300s 0/0

URL Packets Sent and Received Stats:
-----
Message                        Sent      Received
```

```

STATUS_REQUEST      1609      1601
LOOKUP_REQUEST      1526      1526
LOG_REQUEST          0         NA

```

Errors:

-----

```

RFC noncompliant GET method      0
URL buffer update failure        0

```

The following is sample output from the **show url-block** command:

```

hostname# show url-block
      url-block url-mempool 128
      url-block url-size 4
      url-block block 128

```

The following is sample output from the **show url-block block statistics** command:

```

hostname# show url-block block statistics

URL Pending Packet Buffer Stats with max block  128
-----
Cumulative number of packets held:                896
Maximum number of packets held (per URL):          3
Current number of packets held (global):           38
Packets dropped due to
    exceeding url-block buffer limit:              7546
    HTTP server retransmission:                    10
Number of packets released back to client:         0

```

The following is sample output from the **show url-cache stats** command:

```

hostname# show url-cache stats
URL Filter Cache Stats
-----
      Size :      128KB
      Entries :      1724
      In Use :      456
      Lookups :      45
      Hits :      8

```

This shows how the cache is used.

The following is sample output from the **show perfmon** command:

```

hostname# show perfmon
PERFMON STATS:      Current      Average
Xlates              0/s          0/s
Connections         0/s          2/s
TCP Conns           0/s          2/s
UDP Conns           0/s          0/s
URL Access          0/s          2/s
URL Server Req      0/s          3/s
TCP Fixup           0/s          0/s
TCPIntercept        0/s          0/s
HTTP Fixup          0/s          3/s
FTP Fixup           0/s          0/s

AAA Account         0/s          0/s

```

The following is sample output from the **show filter** command:

```

hostname# show filter
filter url http 0.0.0.0 0.0.0.0 0.0.0.0 0.0.0.0

```

## Feature History for URL Filtering

Table 36-6 lists the release history for URL filtering. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

**Table 36-6**      *Feature History for URL Filtering*

| Feature Name  | Platform Releases | Feature Information                                             |
|---------------|-------------------|-----------------------------------------------------------------|
| URL filtering | 7.0(1)            | Filters URLs based on an established set of filtering criteria. |

# CHAPTER 37

## Configuring Digital Certificates

---

This chapter describes how to configure digital certificates and includes the following sections:

- [Information About Digital Certificates, page 37-1](#)
- [Licensing Requirements for Digital Certificates, page 37-8](#)
- [Prerequisites for Certificates, page 37-8](#)
- [Guidelines and Limitations, page 37-8](#)
- [Configuring Digital Certificates, page 37-9](#)
- [Monitoring Digital Certificates, page 37-62](#)
- [Feature History for Certificate Management, page 37-64](#)

## Information About Digital Certificates

CAs are responsible for managing certificate requests and issuing digital certificates. A digital certificate includes information that identifies a user or device, such as a name, serial number, company, department, or IP address. A digital certificate also includes a copy of the public key for the user or device. A CA can be a trusted third party, such as VeriSign, or a private (in-house) CA that you establish within your organization.

### Tip

For an example of a scenario that includes certificate configuration and load balancing, see the following URL:

<https://supportforums.cisco.com/docs/DOC-5964>

This section includes the following topics:

- [Public Key Cryptography, page 37-2](#)
- [Certificate Scalability, page 37-3](#)
- [Key Pairs, page 37-3](#)
- [Trustpoints, page 37-4](#)
- [Revocation Checking, page 37-4](#)
- [The Local CA, page 37-6](#)

## Public Key Cryptography

Digital signatures, enabled by public key cryptography, provide a way to authenticate devices and users. In public key cryptography, such as the RSA encryption system, each user has a key pair containing both a public and a private key. The keys act as complements, and anything encrypted with one of the keys can be decrypted with the other.

In simple terms, a signature is formed when data is encrypted with a private key. The signature is attached to the data and sent to the receiver. The receiver applies the public key of the sender to the data. If the signature sent with the data matches the result of applying the public key to the data, the validity of the message is established.

This process relies on the receiver having a copy of the public key of the sender and a high degree of certainty that this key belongs to the sender, not to someone pretending to be the sender.

Obtaining the public key of a sender is normally handled externally or through an operation performed at installation. For example, most web browsers are configured with the root certificates of several CAs by default. For VPN, the IKE protocol, a component of IPSec, can use digital signatures to authenticate peer devices before setting up security associations.

## Certificate Scalability

Without digital certificates, you must manually configure each IPSec peer for each peer with which it communicates; as a result, each new peer that you add to a network would require a configuration change on each peer with which it needs to communicate securely.

When you use digital certificates, each peer is enrolled with a CA. When two peers try to communicate, they exchange certificates and digitally sign data to authenticate each other. When a new peer is added to the network, you enroll that peer with a CA and none of the other peers need modification. When the new peer attempts an IPSec connection, certificates are automatically exchanged and the peer can be authenticated.

With a CA, a peer authenticates itself to the remote peer by sending a certificate to the remote peer and performing some public key cryptography. Each peer sends its unique certificate, which was issued by the CA. This process works because each certificate encapsulates the public key for the associated peer, each certificate is authenticated by the CA, and all participating peers recognize the CA as an authenticating authority. The process is called IKE with an RSA signature.

The peer can continue sending its certificate for multiple IPSec sessions, and to multiple IPSec peers, until the certificate expires. When its certificate expires, the peer administrator must obtain a new one from the CA.

CAs can also revoke certificates for peers that no longer participate in IPSec. Revoked certificates are not recognized as valid by other peers. Revoked certificates are listed in a CRL, which each peer may check before accepting a certificate from another peer.

Some CAs have an RA as part of their implementation. An RA is a server that acts as a proxy for the CA, so that CA functions can continue when the CA is unavailable.

## Key Pairs

Key pairs are RSA keys, which have the following characteristics:

- RSA keys can be used for SSH or SSL.
- SCEP enrollment supports the certification of RSA keys.

- For the purposes of generating keys, the maximum key modulus for RSA keys is 2048 bits. The default size is 1024. Many SSL connections using identity certificates with RSA key pairs that exceed 1024 bits can cause a high CPU usage on the adaptive security appliance and rejected clientless logins.
- For signature operations, the supported maximum key size is 4096 bits.
- You can generate a general purpose RSA key pair, used for both signing and encryption, or you can generate separate RSA key pairs for each purpose. Separate signing and encryption keys help to reduce exposure of the keys, because SSL uses a key for encryption but not signing. However, IKE uses a key for signing but not encryption. By using separate keys for each, exposure of the keys is minimized.

## Trustpoints

Trustpoints let you manage and track CAs and certificates. A trustpoint is a representation of a CA or identity pair. A trustpoint includes the identity of the CA, CA-specific configuration parameters, and an association with one, enrolled identity certificate.

After you have defined a trustpoint, you can reference it by name in commands requiring that you specify a CA. You can configure many trustpoints.

### Note

If an adaptive security appliance has multiple trustpoints that share the same CA, only one of these trustpoints sharing the CA can be used to validate user certificates. To control which trustpoint sharing a CA is used for validation of user certificates issued by that CA, use the **support-user-cert-validation** command.

For automatic enrollment, a trustpoint must be configured with an enrollment URL, and the CA that the trustpoint represents must be available on the network and must support SCEP.

You can export and import the keypair and issued certificates associated with a trustpoint in PKCS12 format. This format is useful to manually duplicate a trustpoint configuration on a different adaptive security appliance.

## Certificate Enrollment

The adaptive security appliance needs a CA certificate for each trustpoint and one or two certificates for itself, depending upon the configuration of the keys used by the trustpoint. If the trustpoint uses separate RSA keys for signing and encryption, the adaptive security appliance needs two certificates, one for each purpose. In other key configurations, only one certificate is needed.

The adaptive security appliance supports enrollment with SCEP and with manual enrollment, which lets you paste a base-64-encoded certificate directly into the terminal. For site-to-site VPNs, you must enroll each adaptive security appliance. For remote access VPNs, you must enroll each adaptive security appliance and each remote access VPN client.

## Revocation Checking

When a certificate is issued, it is valid for a fixed period of time. Sometimes a CA revokes a certificate before this time period expires; for example, because of security concerns or a change of name or association. CAs periodically issue a signed list of revoked certificates. Enabling revocation checking forces the adaptive security appliance to check that the CA has not revoked a certificate each time that it uses the certificate for authentication.

When you enable revocation checking, the adaptive security appliance checks certificate revocation status during the PKI certificate validation process, which can use either CRL checking, or OCSP, or both. OCSP is *only* used when the first method returns an error (for example, that the server is unavailable).

With CRL checking, the adaptive security appliance retrieves, parses, and caches CRLs, which provide a complete list of revoked certificates. The ASA evaluates certificates against CRLs, also called authority revocation lists, all the way from the identity certificate up the chain of subordinate certificate authorities.

OCSP offers a more scalable method of checking revocation status in that it localizes certificate status through a validation authority, which it queries for status of a specific certificate.

## CRLs

CRLs provide the adaptive security appliance with one way of determining whether a certificate that is within its valid time range has been revoked by the issuing CA. CRL configuration is part of configuration of a trustpoint.

You can configure the adaptive security appliance to make CRL checks mandatory when authenticating a certificate by using the **revocation-check crl** command. You can also make the CRL check optional by using the **revocation-check crl none** command, which allows the certificate authentication to succeed when the CA is unavailable to provide updated CRL data.

The adaptive security appliance can retrieve CRLs from CAs using HTTP, SCEP, or LDAP. CRLs retrieved for each trustpoint are cached for a configurable amount of time for each trustpoint.

When the adaptive security appliance has cached a CRL for longer than the amount of time it is configured to cache CRLs, the adaptive security appliance considers the CRL too old to be reliable, or “stale.” The adaptive security appliance tries to retrieve a newer version of the CRL the next time that a certificate authentication requires a check of the stale CRL.

The adaptive security appliance caches CRLs for an amount of time determined by the following two factors:

- The number of minutes specified with the **cache-time** command. The default value is 60 minutes.
- The NextUpdate field in the CRLs retrieved, which may be absent from CRLs. You control whether the adaptive security appliance requires and uses the NextUpdate field with the **enforcenextupdate** command.

The adaptive security appliance uses these two factors in the following ways:

- If the NextUpdate field is not required, the adaptive security appliance marks CRLs as stale after the length of time defined by the **cache-time** command.
- If the NextUpdate field is required, the adaptive security appliance marks CRLs as stale at the sooner of the two times specified by the **cache-time** command and the NextUpdate field. For example, if the **cache-time** command is set to 100 minutes and the NextUpdate field specifies that the next update is 70 minutes away, the adaptive security appliance marks CRLs as stale in 70 minutes.

If the adaptive security appliance has insufficient memory to store all CRLs cached for a given trustpoint, it deletes the least recently used CRL to make room for a newly retrieved CRL.

## Supported CA Servers

The adaptive security appliance supports the following CA servers:

Cisco IOS CS, the adaptive security appliance local CA, and third-party X.509 compliant CA vendors including, but not limited to:

- Baltimore Technologies
- Entrust
- Digicert
- Geotrust
- Godaddy
- iPlanet/Netscape
- Microsoft Certificate Services
- RSA Keon
- Thawte
- VeriSign

## OCSP

OCSP provides the adaptive security appliance with a way of determining whether a certificate that is within its valid time range has been revoked by the issuing CA. OCSP configuration is part of trustpoint configuration.

OCSP localizes certificate status on a validation authority (an OCSP server, also called the *responder*) which the adaptive security appliance queries for the status of a specific certificate. This method provides better scalability and more up-to-date revocation status than does CRL checking, and helps organizations with large PKI installations deploy and expand secure networks.

### Note

The adaptive security appliance allows a five-second time skew for OCSP responses.

You can configure the adaptive security appliance to make OCSP checks mandatory when authenticating a certificate by using the **revocation-check ocsb** command. You can also make the OCSP check optional by using the **revocation-check ocsb none** command, which allows the certificate authentication to succeed when the validation authority is unavailable to provide updated OCSP data.

OCSP provides three ways to define the OCSP server URL. The adaptive security appliance uses these servers in the following order:

1. The OCSP URL defined in a match certificate override rule by using the **match certificate** command).
2. The OCSP URL configured by using the **ocsb url** command.
3. The AIA field of the client certificate.

**Note**

To configure a trustpoint to validate a self-signed OCSP responder certificate, you import the self-signed responder certificate into its own trustpoint as a trusted CA certificate. Then you configure the **match certificate** command in the client certificate validating trustpoint to use the trustpoint that includes the self-signed OCSP responder certificate to validate the responder certificate. Use the same procedure for configuring validating responder certificates external to the validation path of the client certificate.

The OCSP server (responder) certificate usually signs the OCSP response. After receiving the response, the adaptive security appliance tries to verify the responder certificate. The CA normally sets the lifetime of the OCSP responder certificate to a relatively short period to minimize the chance of being compromised. The CA usually also includes an `ocsp-no-check` extension in the responder certificate, which indicates that this certificate does not need revocation status checking. However, if this extension is not present, the adaptive security appliance tries to check revocation status using the same method specified in the trustpoint. If the responder certificate is not verifiable, revocation checks fail. To avoid this possibility, use the **revocation-check none** command to configure the responder certificate validating trustpoint, and use the **revocation-check ocsp** command to configure the client certificate.

## The Local CA

The local CA performs the following tasks:

- Integrates basic certificate authority operation on the adaptive security appliance.
- Deploys certificates.
- Provides secure revocation checking of issued certificates.
- Provides a certificate authority on the adaptive security appliance for use with browser-based and client-based SSL VPN connections.
- Provides trusted digital certificates to users, without the need to rely on external certificate authorization.
- Provides a secure, in-house authority for certificate authentication and offers straightforward user enrollment by means of a website login.

## Storage for Local CA Files

The adaptive security appliance accesses and implements user information, issued certificates, and revocation lists using a local CA database. This database resides in local flash memory by default, or can be configured to reside on an external file system that is mounted and accessible to the adaptive security appliance.

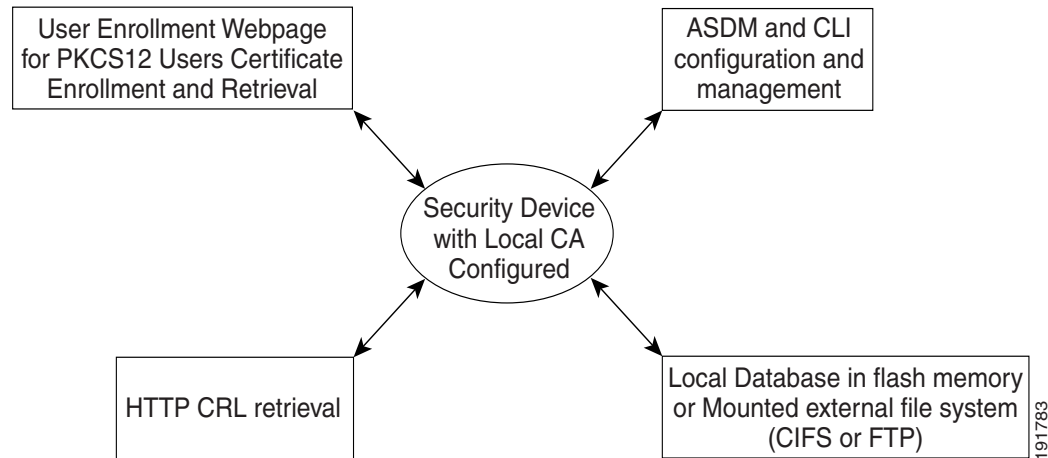

No limits exist on the number of users that can be stored in the local CA user database; however, if flash memory storage issues arise, syslog messages are generated to alert the administrator to take action, and the local CA could be disabled until the storage issues are resolved. Flash memory can store a database with 3500 users or less; however, a database of more than 3500 users requires external storage.

## The Local CA Server

After you configure a local CA server on the adaptive security appliance, users can enroll for a certificate by logging into a website and entering a username and a one-time password that is provided by the local CA administrator to validate their eligibility for enrollment.

As shown in [Figure 37-1](#), the local CA server resides on the adaptive security appliance and handles enrollment requests from website users and CRL inquiries coming from other certificate validating devices and adaptive security appliances. Local CA database and configuration files are maintained either on the adaptive security appliance flash memory (default storage) or on a separate storage device.

**Figure 37-1**      **The Local CA**

## Licensing Requirements for Digital Certificates

The following table shows the licensing requirements for this feature:

| Model      | License Requirement |
|------------|---------------------|
| All models | Base License.       |

## Prerequisites for Certificates

Certificates have the following prerequisites:

- Make sure that the adaptive security appliance is configured correctly to support certificates. An incorrectly configured adaptive security appliance can cause enrollment to fail or request a certificate that includes inaccurate information.
- Make sure that the hostname and domain name of the adaptive security appliance are configured correctly. To view the currently configured hostname and domain name, enter the **show running-config** command. For information about configuring the hostname, see the [“Setting the Hostname” section on page 7-2](#). For information about configuring the domain name, see the [“Setting the Date and Time” section on page 7-3](#).
- Make sure that the adaptive security appliance clock is set accurately before configuring the CA. Certificates have a date and time that they become valid and expire. When the adaptive security appliance enrolls with a CA and obtains a certificate, the adaptive security appliance checks that the current time is within the valid range for the certificate. If it is outside that range, enrollment fails. For information about setting the clock, see the [“Setting the Date and Time” section on page 7-3](#).

# Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

## Context Mode Guidelines

Supported in single and multiple context mode.

## Firewall Mode Guidelines

Supported in routed and transparent mode.

## Failover Guidelines

Does not support replicating sessions in Stateful Failover.

## IPv6 Guidelines

Supports IPv6.

## Additional Guidelines

For adaptive security appliances that are configured as CA servers or clients, limit the validity period of the certificate to less than the recommended end date of 03:14:08 UTC, January 19, 2038. This guideline also applies to imported certificates from third-party vendors.

# Configuring Digital Certificates

The following list shows the order in which you must perform tasks to configure digital certificates:

- [Configuring Key Pairs, page 37-12](#)
- [Removing Key Pairs, page 37-12](#)
- [Configuring Trustpoints, page 37-13](#)
- [Configuring CRLs for a Trustpoint, page 37-15](#)
- [Exporting a Trustpoint Configuration, page 37-17](#)
- [Importing a Trustpoint Configuration, page 37-18](#)
- [Configuring CA Certificate Map Rules, page 37-19](#)
- [Obtaining Certificates Manually, page 37-19](#)
- [Obtaining Certificates Automatically with SCEP, page 37-22](#)
- [Enabling the Local CA Server, page 37-23](#)
- [Configuring the Local CA Server, page 37-24](#)
- [Customizing the Local CA Server, page 37-26](#)
- [Debugging the Local CA Server, page 37-28](#)
- [Disabling the Local CA Server, page 37-28](#)
- [Deleting the Local CA Server, page 37-28](#)
- [Configuring Local CA Certificate Characteristics, page 37-29](#)

## Configuring Key Pairs

To generate key pairs, perform the following steps:

|        | Command                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto key generate rsa</b><br><br><b>Example:</b><br>hostname/contexta(config)# crypto key generate rsa                                     | Generates one, general-purpose RSA key pair. The default key modulus is 1024. To specify other modulus sizes, use the <b>modulus</b> keyword.<br><br><b>Note</b> Many SSL connections using identity certificates with RSA key pairs that exceed 1024 bits can cause high CPU usage on the adaptive security appliance and rejected clientless logins. |
| Step 2 | <b>crypto key generate rsa label key-pair-label</b><br><br><b>Example:</b><br>hostname/contexta(config)# crypto key generate rsa label exchange | (Optional) Assigns a label to each key pair. The label is referenced by the trustpoint that uses the key pair. If you do not assign a label, the key pair is automatically labeled, <i>Default-RSA-Key</i> .                                                                                                                                           |
| Step 3 | <b>show crypto key name of key</b><br><br><b>Example:</b><br>hostname/contexta(config)# show crypto key examplekey                              | Verifies key pairs that you have generated.                                                                                                                                                                                                                                                                                                            |
| Step 4 | <b>write memory</b><br><br><b>Example:</b><br>hostname(config)# write memory                                                                    | Saves the key pair that you have generated.                                                                                                                                                                                                                                                                                                            |

## Removing Key Pairs

To remove key pairs, perform the following steps:

| Command                                                                                          | Purpose            |
|--------------------------------------------------------------------------------------------------|--------------------|
| <b>crypto key zeroize rsa</b><br><br><b>Example:</b><br>hostname(config)# crypto key zeroize rsa | Removes key pairs. |

### Examples

The following example shows how to remove key pairs:

```
hostname(config)# crypto key zeroize rsa
WARNING: All RSA keys will be removed.
WARNING: All device certs issued using these keys will also be removed.

Do you really want to remove these keys? [yes/no] y
```

## Configuring Trustpoints

To configure a trustpoint, perform the following steps:

|               | Command                                                                                                                                                                                                                                                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                    |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>crypto ca trustpoint</b> <i>trustpoint-name</i><br><br><b>Example:</b><br>hostname/contexta(config)# crypto ca trustpoint Main                                                                                                                                                                                                                                                       | Creates a trustpoint that corresponds to the CA from which the adaptive security appliance needs to receive a certificate. Enters the crypto ca trustpoint configuration mode, which controls CA-specific trustpoint parameters that you may configure starting in Step 3. |
| <b>Step 2</b> | Choose one of the following options:                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                                            |
|               | <b>enrollment url</b> <i>url</i><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# enrollment url http://10.29.67.142:80/certsrv/mscep/mscep.dll                                                                                                                                                                                                                       | Requests automatic enrollment using SCEP with the specified trustpoint and configures the enrollment URL.                                                                                                                                                                  |
|               | <b>enrollment terminal</b><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# enrollment terminal                                                                                                                                                                                                                                                                       | Requests manual enrollment with the specified trustpoint by pasting the certificate received from the CA into the terminal.                                                                                                                                                |
| <b>Step 3</b> | <b>revocation-check</b> <i>crl</i> <i>none</i><br><b>revocation-check</b> <i>crl</i><br><b>revocation-check</b> <i>none</i><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# revocation-check <i>crl</i> <i>none</i><br>hostname/contexta(config-ca-trustpoint)# revocation-check <i>crl</i><br>hostname/contexta(config-ca-trustpoint)# revocation-check <i>none</i> | Specifies the available CRL configuration options.<br><br><b>Note</b> To enable either required or optional CRL checking, make sure that you configure the trustpoint for CRL management after obtaining certificates.                                                     |
| <b>Step 4</b> | <b>crl configure</b><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# crl configure                                                                                                                                                                                                                                                                                   | Enters crl configuration mode.                                                                                                                                                                                                                                             |
| <b>Step 5</b> | <b>email</b> <i>address</i><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# email example.com                                                                                                                                                                                                                                                                        | During enrollment, asks the CA to include the specified e-mail address in the Subject Alternative Name extension of the certificate.                                                                                                                                       |
| <b>Step 6</b> | <b>enrollment retry period</b><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# enrollment retry period 5                                                                                                                                                                                                                                                             | (Optional) Specifies a retry period in minutes, and applies <i>only</i> to SCEP enrollment.                                                                                                                                                                                |

|         | Command                                                                                                                                                          | Purpose                                                                                                                                                                                                      |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 7  | <b>enrollment retry count</b><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# enrollment<br>retry period 2                                    | (Optional) Specifies a maximum number of permitted retries, and applies <i>only</i> to SCEP enrollment.                                                                                                      |
| Step 8  | <b>fqdn fqdn</b><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# fqdn<br>example.com                                                          | During enrollment, asks the CA to include the specified fully qualified domain name in the Subject Alternative Name extension of the certificate.                                                            |
| Step 9  | <b>ip-address ip-address</b><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# ip-address<br>10.10.100.1                                        | During enrollment, asks the CA to include the IP address of the adaptive security appliance in the certificate.                                                                                              |
| Step 10 | <b>keypair name</b><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# keypair<br>exchange                                                       | Specifies the key pair whose public key is to be certified.                                                                                                                                                  |
| Step 11 | <b>match certificate map-name override ocsp</b><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# match<br>certificate examplemap override ocsp | Configures OCSP URL overrides and trustpoints to use for validating OCSP responder certificates.                                                                                                             |
| Step 12 | <b>ocsp disable-nonce</b><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# ocsp<br>disable-nonce                                               | Disables the nonce extension on an OCSP request. The nonce extension cryptographically binds requests with responses to avoid replay attacks.                                                                |
| Step 13 | <b>ocsp url</b><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# ocsp url                                                                      | Configures an OCSP server for the adaptive security appliance to use to check all certificates associated with a trustpoint rather than the server specified in the AIA extension of the client certificate. |
| Step 14 | <b>password string</b><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# password<br>mypassword                                                 | Specifies a challenge phrase that is registered with the CA during enrollment. The CA usually uses this phrase to authenticate a subsequent revocation request.                                              |
| Step 15 | <b>revocation check</b><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# revocation<br>check                                                   | Sets one or more methods for revocation checking: CRL, OCSP, and none.                                                                                                                                       |

|                | Command                                                                                                                              | Purpose                                                                                                                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 16</b> | <b>subject-name</b> <i>X.500 name</i><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# myname<br>X.500 exemplename | During enrollment, asks the CA to include the specified subject DN in the certificate. If a DN string includes a comma, enclose the value string within double quotes (for example, O="Company, Inc.>"). |
| <b>Step 17</b> | <b>serial-number</b><br><br><b>Example:</b><br>hostname/contexta(config-ca-trustpoint)# serial<br>number JMX1213L2A7                 | During enrollment, asks the CA to include the adaptive security appliance serial number in the certificate.                                                                                              |
| <b>Step 18</b> | <b>write memory</b><br><br><b>Example:</b><br>hostname/contexta(config)# write memory                                                | Saves the running configuration.                                                                                                                                                                         |

## Configuring CRLs for a Trustpoint

To use mandatory or optional CRL checking during certificate authentication, you must configure CRLs for each trustpoint. To configure CRLs for a trustpoint, perform the following steps:

|               | Command                                                                                                                   | Purpose                                                                                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>crypto ca trustpoint</b> <i>trustpoint-name</i><br><br><b>Example:</b><br>hostname (config)# crypto ca trustpoint Main | Enters crypto ca trustpoint configuration mode for the trustpoint whose CRL configuration you want to modify.<br><br><b>Note</b> Make sure that you have enabled CRLs before entering this command. In addition, the CRL must be available for authentication to succeed. |
| <b>Step 2</b> | <b>crl configure</b><br><br><b>Example:</b><br>hostname (config-ca-trustpoint)# crl configure                             | Enters crl configuration mode for the current trustpoint.<br><br><b>Tip</b> To set all CRL configuration parameters to default values, use the <b>default</b> command. At any time during CRL configuration, reenter this command to restart the procedure.               |
| <b>Step 3</b> | Do one of the following:<br><br><b>policy cdp</b><br><br><b>Example:</b><br>hostname (config-ca-crl)# policy cdp          | Configures retrieval policy. CRLs are retrieved only from the CRL distribution points specified in authenticated certificates.<br><br><b>Note</b> SCEP retrieval is not supported by distribution points specified in certificates.<br><br>To continue, go to Step 5.     |

|               | Command                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <b>policy static</b><br><br><b>Example:</b><br>hostname (config-ca-crl)# policy static               | Configures retrieval policy. CRLs are retrieved only from URLs that you configure.<br><br>To continue, go to Step 4.                                                                                                                                                                                                                                                                                                                                                       |
|               | <b>policy both</b><br><br><b>Example:</b><br>hostname (config-ca-crl)# policy both                   | Configures retrieval policy. CRLs are retrieved from CRL distribution points specified in authenticated certificates and from URLs that you configure.<br><br>To continue, go to Step 4.                                                                                                                                                                                                                                                                                   |
| <b>Step 4</b> | <b>url n url</b><br><br><b>Example:</b><br>hostname (config-ca-crl)# url 2<br>http://www.example.com | If you used the keywords <b>static</b> or <b>both</b> when you configured the CRL policy, you must configure URLs for CRL retrieval. You can enter up to five URLs, ranked 1 through 5. The <i>n</i> is the rank assigned to the URL. To remove a URL, use the <b>no url n</b> command.                                                                                                                                                                                    |
| <b>Step 5</b> | <b>protocol http   ldap   scep</b><br><br><b>Example:</b><br>hostname (config-ca-crl)# protocol http | Configures the retrieval method. Specifies HTTP, LDAP, or SCEP as the CRL retrieval method.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 6</b> | <b>cache-time refresh-time</b><br><br><b>Example:</b><br>hostname (config-ca-crl)# cache-time 420    | Configures how long the adaptive security appliance caches CRLs for the current trustpoint. <i>refresh-time</i> is the number of minutes that the adaptive security appliance waits before considering a CRL stale.                                                                                                                                                                                                                                                        |
| <b>Step 7</b> | Do one of the following:                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|               | <b>enforcenextupdate</b><br><br><b>Example:</b><br>hostname (config-ca-crl)# enforcenextupdate       | Requires the NextUpdate field in CRLs. This is the default setting.                                                                                                                                                                                                                                                                                                                                                                                                        |
|               | <b>no enforcenextupdate</b><br><br><b>Example:</b><br>hostname (config-ca-crl)# no enforcenextupdate | Allows the NextUpdate field to be absent in CRLs.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Step 8</b> | <b>ldap-defaults server</b><br><br><b>Example:</b><br>hostname (config-ca-crl)# ldap-defaults ldap1  | Identifies the LDAP server to the adaptive security appliance if LDAP is specified as the retrieval protocol. You can specify the server by DNS hostname or by IP address. You can also provide a port number if the server listens for LDAP queries on a port other than the default of 389.<br><br><b>Note</b> If you use a hostname instead of an IP address to specify the LDAP server, make sure that you have configured the adaptive security appliance to use DNS. |

|         | Command                                                                                                                                           | Purpose                                                                                                                                   |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| Step 9  | <b>ldap-dn</b> <i>admin-DN password</i><br><br><b>Example:</b><br>hostname (config-ca-crl)# ldap-dn<br>cn=admin,ou=devtest,o=engineering c00lRunZ | Allows CRL retrieval if the LDAP server requires credentials.                                                                             |
| Step 10 | <b>crypto ca crl request</b> <i>trustpoint</i><br><br><b>Example:</b><br>hostname (config-ca-crl)# crypto ca crl request Main                     | Retrieves the current CRL from the CA represented by the specified trustpoint and tests the CRL configuration for the current trustpoint. |
| Step 11 | <b>write memory</b><br><br><b>Example:</b><br>hostname (config)# write memory                                                                     | Saves the running configuration.                                                                                                          |

## Exporting a Trustpoint Configuration

To export a trustpoint configuration, enter the following command:

| Command                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>crypto ca export</b> <i>trustpoint</i><br><br><b>Example:</b><br>hostname(config)# crypto ca export Main | Exports a trustpoint configuration with all associated keys and certificates in PKCS12 format. The adaptive security appliance displays the PKCS12 data in the terminal. You can copy the data. The trustpoint data is password protected; however, if you save the trustpoint data in a file, make sure that the file is in a secure location. |

### Examples

The following example exports PKCS12 data for the trustpoint Main with the passphrase Wh0zits:

```
hostname (config)# crypto ca export Main pkcs12 Wh0zits
```

Exported pkcs12 follows:

```
[ PKCS12 data omitted ]
```

```
---End - This line not part of the pkcs12---
```

## Importing a Trustpoint Configuration

To import a trustpoint configuration, enter the following command:

| Command                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>crypto ca import trustpoint pkcs12</b><br><br><b>Example:</b><br><pre>hostname(config)# crypto ca import Main pkcs12</pre> | Imports keypairs and issued certificates that are associated with a trustpoint configuration. The adaptive security appliance prompts you to paste the text into the terminal in base 64 format. The key pair imported with the trustpoint is assigned a label that matches the name of the trustpoint that you create.<br><br><b>Note</b> If an adaptive security appliance has trustpoints that share the same CA, you can use only one of the trustpoints that share the CA to validate user certificates. To control which trustpoint that shares a CA is used for validation of user certificates issued by that CA, use the <b>support-user-cert-validation</b> keyword. |

### Examples

The following example manually imports PKCS12 data to the trustpoint Main with the passphrase Wh0zits:

```
hostname (config)# crypto ca import Main pkcs12 Wh0zits

Enter the base 64 encoded pkcs12.
End with a blank line or the word "quit" on a line by itself:
[ PKCS12 data omitted ]
quit
INFO: Import PKCS12 operation completed successfully
```

The following example manually imports a certificate for the trustpoint Main:

```
hostname (config)# crypto ca import Main certificate
% The fully-qualified domain name in the certificate will be:
securityappliance.example.com

Enter the base 64 encoded certificate.
End with a blank line or the word "quit" on a line by itself
[ certificate data omitted ]
quit
INFO: Certificate successfully imported
```

## Configuring CA Certificate Map Rules

You can configure rules based on the Issuer and Subject fields of a certificate. Using the rules you create, you can map IPSec peer certificates to tunnel groups with the **tunnel-group-map** command. The adaptive security appliance supports one CA certificate map, which can include many rules.

To configure a CA certificate map rule, perform the following steps:

|        | Command                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto ca certificate map</b> <i>sequence-number</i><br><br><b>Example:</b><br>hostname(config)# crypto ca certificate map 1                     | Enters CA certificate map configuration mode for the rule you want to configure and specifies the rule index number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 2 | <b>issuer-name</b> <i>DN-string</i><br><br><b>Example:</b><br>hostname(config-ca-cert-map)# issuer-name cn=asa.example.com                          | Specifies the distinguished name of all issued certificates, which is also the subject-name DN of the self-signed CA certificate. Use commas to separate attribute-value pairs. Insert quotation marks around any value that includes a comma. An issuer-name must be less than 500 alphanumeric characters. The default issuer-name is cn= <i>hostname.domain-name</i> .                                                                                                                                                                                                                                                                                                                                                       |
| Step 3 | <b>subject-name attr</b> <i>tag eq   co   ne   nc string</i><br><br><b>Example:</b><br>hostname(config-ca-cert-map)# subject-name attr cn eq mycert | Specifies tests that the adaptive security appliance can apply to values found in the Subject field of certificates. The tests can apply to specific attributes or to the entire field. You can configure many tests per rule, and all the tests you specify with these commands must be true for a rule to match a certificate. The following are valid operators: <ul style="list-style-type: none"> <li>• eq—The field or attribute must be identical to the value given.</li> <li>• ne—The field or attribute cannot be identical to the value given.</li> <li>• co—Part or all of the field or attribute must match the value given.</li> <li>• nc—No part of the field or attribute can match the value given.</li> </ul> |
| Step 4 | <b>write memory</b><br><br><b>Example:</b><br>hostname (config)# write memory                                                                       | Saves the running configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Obtaining Certificates Manually

### Note

When you configure the trustpoint, use of the **enrollment terminal** command determines whether or not you must obtain certificates manually.

To obtain certificates manually, perform the following steps:

|               | Command                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <code>crypto ca authenticate trustpoint</code><br><br><b>Example:</b><br>hostname (config)# <code>crypto ca authenticate Main</code>             | Obtains a base 64, encoded CA certificate from the CA represented by the trustpoint.                                                                                                                                                                                                                                                                                                                                          |
| <b>Step 2</b> | <code>crypto ca enroll trustpoint</code><br><br><b>Example:</b><br>hostname (config)# <code>crypto ca enroll Main</code>                         | Generates a certificate request.<br><br>If you use separate RSA keys for signing and encryption, the output of the <b>crypto ca enroll</b> command displays two certificate requests, one for each key. To complete enrollment, obtain a certificate for each certificate request generated by the <b>crypto ca enroll</b> command. Make sure that the certificate is in base 64 format.                                      |
| <b>Step 3</b> | <code>crypto ca import trustpoint certificate</code><br><br><b>Example:</b><br>hostname (config)# <code>crypto ca import Main certificate</code> | Prompts you to paste each certificate that you receive from the CA into the terminal in base-64 format.<br><br>If you use separate RSA key pairs for signing and encryption, perform this step for each certificate separately. The adaptive security appliance determines automatically whether the certificate is for the signing or encryption key pair. The order in which you import the two certificates has no effect. |
| <b>Step 4</b> | <code>show crypto ca server certificate</code><br><br><b>Example:</b><br>hostname (config)# <code>show crypto ca server certificate Main</code>  | Verifies that the enrollment process was successful and shows details of the certificate issued for the adaptive security appliance and the CA certificate for the trustpoint.                                                                                                                                                                                                                                                |
| <b>Step 5</b> | <code>write memory</code><br><br><b>Example:</b><br>hostname (config)# <code>write memory</code>                                                 | Saves the running configuration.                                                                                                                                                                                                                                                                                                                                                                                              |

Repeat these steps for each trustpoint that you configure for manual enrollment. When you have completed this procedure, the adaptive security appliance will have received a CA certificate for the trustpoint and one or two certificates for signing and encryption purposes. If you use general-purpose RSA keys, the certificate received is for signing and encryption. If you use separate RSA keys for signing and encryption, the certificates received are used for each purpose exclusively.

## Examples

The following example shows a CA certificate request for the trustpoint Main:

```
hostname (config)# crypto ca authenticate Main
Enter the base 64 encoded CA certificate.
End with a blank line or the word "quit" on a line by itself
MIIDRTCCAu+gAwIBAgIQKVCqP/KW74VP0NZzL+JbRTANBgqhkiG9w0BAQUFADCB
```

```
[ certificate data omitted ]
/7QEM8izy0EOTSErKu7Nd76jwf5e4qttkQ==
quit

INFO: Certificate has the following attributes:
Fingerprint:      24b81433 409b3fd5 e5431699 8d490d34
Do you accept this certificate? [yes/no]: y
Trustpoint CA certificate accepted.

% Certificate successfully imported
```

The following example shows a certificate and encryption key request for the trustpoint Main, which is configured to use manual enrollment and general-purpose RSA keys for signing and encryption:

```
hostname (config)# crypto ca enroll Main
% Start certificate enrollment...

% The fully-qualified domain name in the certificate will be:
securityappliance.example.com

% Include the device serial number in the subject name? [yes/no]: n

Display Certificate Request to terminal? [yes/no]: y
Certificate Request follows:

## Obtaining Certificates Automatically with SCEP

To obtain certificates automatically using SCEP, perform the following steps:

|        | Command                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto ca authenticate</b> <i>trustpoint</i><br><br><b>Example:</b><br><pre>hostname/contexta(config)# crypto ca authenticate Main</pre> | <p>Obtains the CA certificate for the configured trustpoint.</p> <p><b>Note</b> This step assumes that you have already obtained a base-64 encoded CA certificate from the CA represented by the trustpoint.</p> <p>When you configure the trustpoint, use of the <b>enrollment url</b> command determines whether or not you must obtain certificates automatically via SCEP. For more information, see the <a href="#">“Configuring Trustpoints”</a> section on page 37-13.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 2 | <b>crypto ca enroll</b> <i>trustpoint</i><br><br><b>Example:</b><br><pre>hostname/contexta(config)# crypto ca enroll Main</pre>             | <p>Enrolls the adaptive security appliance with the trustpoint. Retrieves a certificate for signing data and depending on the type of keys that you have configured, for encrypting data. Before entering this command, contact the CA administrator, who may need to authenticate the enrollment request manually before the CA grants certificates.</p> <p>If the adaptive security appliance does not receive a certificate from the CA within one minute (the default) of sending a certificate request, it resends the certificate request. The adaptive security appliance continues sending a certificate request each minute until a certificate is received.</p> <p>If the fully qualified domain name configured for the trustpoint is not identical to the fully qualified domain name of the adaptive security appliance, including the case of the characters, a warning appears. To resolve this issue, exit the enrollment process, make any necessary corrections, and reenter the <b>crypto ca enroll</b> command.</p> <p><b>Note</b> If the adaptive security appliance reboots after you have issued the <b>crypto ca enroll</b> command but before you have received the certificate, reenter the <b>crypto ca enroll</b> command and notify the CA administrator.</p> |

|               | Command                                                                                                                              | Purpose                                                                                                                                                                     |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <b>show crypto ca server certificate</b><br><br><b>Example:</b><br>hostname/contexta(config)# show crypto ca server certificate Main | Verifies that the enrollment process was successful by displaying certificate details issued for the adaptive security appliance and the CA certificate for the trustpoint. |
| <b>Step 4</b> | <b>write memory</b><br><br><b>Example:</b><br>hostname/contexta(config)# write memory                                                | Saves the running configuration.                                                                                                                                            |

## Enabling the Local CA Server

Before enabling the local CA server, you must first create a passphrase of at least seven characters to encode and archive a PKCS12 file that includes the local CA certificate and keypair to be generated. The passphrase unlocks the PKCS12 archive if the CA certificate or keypair is lost.

To enable the local CA server, perform the following steps:

|               | Command                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|---------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server | Enters local ca server configuration mode. Allows you to configure and manage a local CA.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 2</b> | <b>no shutdown</b><br><br><b>Example:</b><br>hostname (config-ca-server)# no shutdown | Enables the local CA server. Generates the local CA server certificate, keypair and necessary database files, and archives the local CA server certificate and keypair to storage in a PKCS12 file. Requires an 8-65 alphanumeric character password. After initial startup, you can disable the local CA without being prompted for the passphrase.<br><br><b>Note</b> After you enable the local CA server, save the configuration to make sure that the local CA certificate and keypair are not lost after a reboot occurs. |

### Examples

The following example enables the local CA server:

```
hostname (config)# crypto ca server
hostname (config-ca-server)# no shutdown

% Some server settings cannot be changed after CA certificate generation.
% Please enter a passphrase to protect the private key
% or type Return to exit

Password: caserver

Re-enter password: caserver
```

Keypair generation process begin. Please wait...

The following is sample output that shows local CA server configuration and status:

```
Certificate Server LOCAL-CA-SERVER:
  Status: enabled
  State: enabled
  Server's configuration is locked (enter "shutdown" to unlock it)
  Issuer name: CN=wz5520-1-16
  CA certificate fingerprint/thumbprint: (MD5)
    76dd1439 ac94fdbc 74a0a89f cb815acc
  CA certificate fingerprint/thumbprint: (SHA1)
    58754ffd 9f19f9fd b13b4b02 15b3e4be b70b5a83
  Last certificate issued serial number: 0x6
  CA certificate expiration timer: 14:25:11 UTC Jan 16 2008
  CRL NextUpdate timer: 16:09:55 UTC Jan 24 2007
  Current primary storage dir: flash:
```

## Configuring the Local CA Server

To configure the local CA server, perform the following steps:

|        | Command                                                                                                                                         | Purpose                                                                                                                                                                                |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server                                                           | Enters local CA server configuration mode.<br>Generates the local CA.                                                                                                                  |
| Step 2 | <b>smtp from-address e-mail_address</b><br><br><b>Example:</b><br>hostname (config-ca-server) # smtp from-address<br>SecurityAdmin@hostcorp.com | Specifies the SMTP from-address, a valid e-mail address that the local CA uses as a from address when sending e-mail messages that deliver OTPs for an enrollment invitation to users. |

|               | Command                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <b>subject-name-default dn</b><br><br><b>Example:</b><br><br><pre>hostname (config-ca-server)# subject-name-default cn=engineer, o=asc systems, c="US"</pre> | <p>(Optional) Specifies the subject-name DN that is appended to each username on issued certificates.</p> <p>The subject-name DN and the username combine to form the DN in all user certificates that are issued by the local CA server. If you do not specify a subject-name DN, you must specify the exact subject name DN to be included in a user certificate each time that you add a user to the user database.</p> <p><b>Note</b> Make sure that you review all optional parameters carefully before you enable the configured local CA, because you cannot change issuer-name and keysize server values after you enable the local CA for the first time.</p> |
| <b>Step 4</b> | <b>no shutdown</b><br><br><b>Example:</b><br><br><pre>hostname (config-ca-server)# no shutdown</pre>                                                         | <p>Creates the self-signed certificate and associates it with the local CA on the adaptive security appliance. The self-signed certificate key usage extension has key encryption, key signature, CRL signing, and certificate signing capabilities.</p> <p><b>Note</b> After the self-signed local CA certificate has been generated, to change any characteristics, you must delete the existing local CA server and completely recreate it.</p> <p>The local CA server keeps track of user certificates, so the administrator can revoke or restore privileges as needed.</p>                                                                                       |

## Examples

The following example shows how to configure and enable the local CA server using the predefined default values for all required parameters:

```
hostname (config)# crypto ca server
hostname (config-ca-server) # smtp from-address SecurityAdmin@hostcorp.com
hostname (config-ca-server) # subject-name-default cn=engineer, o=asc Systems, c=US
hostname (config-ca-server) # no shutdown
```

## Customizing the Local CA Server

To configure a customized local CA server, perform the following steps:

|        | Command                                                                                                                                                                                               | Purpose                                                                                                    |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto ca server</b><br><br><b>Example:</b><br><pre>hostname (config)# crypto ca server</pre>                                                                                                      | Enters local CA server configuration mode. Allows you to configure and manage a local CA.                  |
| Step 2 | <b>issuer-name</b> <i>DN-string</i><br><br><b>Example:</b><br><pre>hostname (config-ca-server)# issuer-name cn=xx5520,cn=30.132.0.25,ou=DevTest,ou=QA,o=ASC Systems</pre>                             | Specifies parameters that do not have default values.                                                      |
| Step 3 | <b>smtp subject</b> <i>subject-line</i><br><br><b>Example:</b><br><pre>hostname (config-ca-server) # smtp subject Priority E-Mail: Enclosed Confidential Information is Required for Enrollment</pre> | Customizes the text that appears in the subject field of all e-mail messages sent from the local CA server |

|               | Command                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 4</b> | <b>smtp from-address</b> <i>e-mail_address</i><br><br><b>Example:</b><br><br><pre>hostname (config-ca-server) # smtp from-address SecurityAdmin@hostcorp.com</pre> | Specifies the e-mail address that is to be used as the From: field of all e-mail messages that are generated by the local CA server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Step 5</b> | <b>subject-name-default</b> <i>dn</i><br><br><b>Example:</b><br><br><pre>hostname (config-ca-server) # subject-name default cn=engineer, o=ASC Systems, c=US</pre> | <p>Specifies an optional subject-name DN to be appended to a username on issued certificates. The default subject-name DN becomes part of the username in all user certificates issued by the local CA server.</p> <p>The allowed DN attribute keywords are as follows:</p> <ul style="list-style-type: none"> <li>• C = Country</li> <li>• CN= Common Name</li> <li>• EA = E-mail Address</li> <li>• L = Locality</li> <li>• O = Organization Name</li> <li>• OU = Organization Unit</li> <li>• ST = State/Province</li> <li>• SN = Surname</li> <li>• ST = State/Province</li> </ul> <p><b>Note</b> If you do not specify a subject-name-default to serve as a standard subject-name default, you must specify a DN each time that you add a user.</p> |

## Debugging the Local CA Server

To debug the newly configured local CA server, perform the following steps:

|        | Command                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                         |
|--------|-------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server                       | Enters local ca server configuration mode. Allows you to configure and manage a local CA.                                                                                                                                                                                                                                                                       |
| Step 2 | <b>debug crypto ca server</b><br><br><b>Example:</b><br>hostname (config-ca-server)# debug crypto ca server | Displays debugging messages when you configure and enable the local CA server. Performs level 1 debugging functions; levels 1-255 are available.<br><br><b>Note</b> Debugging commands might slow down traffic on busy networks. Levels 5 and higher are reserved for raw data dumps and should be avoided during normal debugging because of excessive output. |

## Disabling the Local CA Server

To disable the local CA server, perform the following steps:

|        | Command                                                                                                                     | Purpose                                                                                                                                                                                                                                                                        |
|--------|-----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server                                       | Enters local ca server configuration mode. Allows you to configure and manage a local CA.                                                                                                                                                                                      |
| Step 2 | <b>shutdown</b><br><br><b>Example:</b><br>hostname (config-ca-server)# shutdown<br>INFO: Local CA Server has been shutdown. | Disables the local CA server. Disables website enrollment and allows you to modify the local CA server configuration. Stores the current configuration and associated files. After initial startup, you can reenabling the local CA without being prompted for the passphrase. |

## Deleting the Local CA Server

To delete an existing local CA server (either enabled or disabled), enter one of the following commands:

| Command                  | Purpose |
|--------------------------|---------|
| Do one of the following: |         |

| Command                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>no crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# no crypto ca server                        | <b>Purpose</b> Removes an existing local CA server (either enabled or disabled).<br><br><b>Note</b> Deleting the local CA server removes the configuration from the adaptive security appliance. After the configuration has been deleted, it is unrecoverable.<br><br>Make sure that you also delete the associated local CA server database and configuration files (that is, all files with the wildcard name, LOCAL-CA-SERVER.*). |
| <b>clear configure crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# clear config crypto ca server |                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Configuring Local CA Certificate Characteristics

You can configure the following characteristics of local CA certificates:

- The name of the certificate issuer as it appears on all user certificates.
- The lifetime of the local CA certificates (server and user) and the CRL.
- The length of the public and private keypairs associated with local CA and user certificates.

This section includes the following topics:

- [Configuring the Issuer Name, page 37-30](#)
- [Configuring the CA Certificate Lifetime, page 37-30](#)
- [Configuring the User Certificate Lifetime, page 37-32](#)
- [Configuring the CRL Lifetime, page 37-32](#)
- [Configuring the Server Keysize, page 37-33](#)
- [Setting Up External Local CA File Storage, page 37-34](#)
- [Downloading CRLs, page 37-36](#)
- [Storing CRLs, page 37-37](#)
- [Maintaining the Local CA Certificate Database, page 37-43](#)
- [Adding and Enrolling Users, page 37-39](#)
- [Renewing Users, page 37-41](#)
- [Restoring Users, page 37-42](#)
- [Removing Users, page 37-42](#)
- [Revoking Certificates, page 37-43](#)
- [Maintaining the Local CA Certificate Database, page 37-43](#)
- [Rolling Over Local CA Certificates, page 37-43](#)

## Configuring the Issuer Name

To configure the certificate issuer name, perform the following steps:

|               | Command                                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>crypto ca server</b><br><br><b>Example:</b><br><pre>hostname (config)# crypto ca server</pre>                                                                          | Enters local CA server configuration mode. Allows you to configure and manage a local CA.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 2</b> | <b>issuer-name</b> <i>DN-string</i><br><br><b>Example:</b><br><pre>hostname (config-ca-server)# issuer-name CN=xx5520,CN=30.132.0.25,ou=DevTest,ou=QA,O=ABC Systems</pre> | <p>Specifies the local CA certificate subject name. The configured certificate issuer name is both the subject name and issuer name of the self-signed local CA certificate, as well as the issuer name in all issued client certificates and in the issued CRL. The default issuer name in the local CA is in the format, <i>hostname.domainname</i>.</p> <p><b>Note</b> You cannot change the issuer name value after the local CA is first enabled.</p> |

## Configuring the CA Certificate Lifetime

To configure the local CA server certificate lifetime, perform the following steps:

|               | Command                                                                                          | Purpose                                                                                   |
|---------------|--------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>crypto ca server</b><br><br><b>Example:</b><br><pre>hostname (config)# crypto ca server</pre> | Enters local CA server configuration mode. Allows you to configure and manage a local CA. |

|               | Command                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <p><b>lifetime ca-certificate time</b></p> <p><b>Example:</b></p> <pre>hostname (config-ca-server)# lifetime ca-certificate 365</pre> | <p>Determines the expiration date included in the certificate. The default lifetime of a local CA certificate is three years.</p> <p>Make sure that you limit the validity period of the certificate to less than the recommended end date of 03:14:08 UTC, January 19, 2038.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 3</b> | <p><b>no lifetime ca-certificate</b></p> <p><b>Example:</b></p> <pre>hostname (config-ca-server)# no lifetime ca-certificate</pre>    | <p>(Optional) Resets the local CA certificate lifetime to the default value of three years.</p> <p>The local CA server automatically generates a replacement CA certificate 30 days before it expires, which allows the replacement certificate to be exported and imported onto any other devices for certificate validation of user certificates that have been issued by the local CA certificate after the current local CA certificate has expired. The following preexpiration syslog message is generated:</p> <pre>%ASA-1-717049: Local CA Server certificate is due to expire in days days and a replacement certificate is available for export.</pre> <p><b>Note</b> When notified of this automatic rollover, the administrator must make sure that the new local CA certificate is imported onto all required devices before it expires.</p> |

## Configuring the User Certificate Lifetime

To configure the user certificate lifetime, perform the following steps:

|        | Command                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|-----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server                           | Enters local CA server configuration mode. Allows you to configure and manage a local CA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 2 | <b>lifetime certificate time</b><br><br><b>Example:</b><br>hostname (config-ca-server)# lifetime certificate 60 | Sets the length of time that you want user certificates to remain valid.<br><br><b>Note</b> Before a user certificate expires, the local CA server automatically initiates certificate renewal processing by granting enrollment privileges to the user several days ahead of the certificate expiration date, setting renewal reminders, and delivering an e-mail message that includes the enrollment username and OTP for certificate renewal. Make sure that you limit the validity period of the certificate to less than the recommended end date of 03:14:08 UTC, January 19, 2038. |

## Configuring the CRL Lifetime

To configure the CRL lifetime, perform the following steps:

|        | Command                                                                               | Purpose                                                                                   |
|--------|---------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server | Enters local CA server configuration mode. Allows you to configure and manage a local CA. |

|               | Command                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>lifetime crl time</b><br><br><b>Example:</b><br><br><pre>hostname (config-ca-server)# lifetime crl 10</pre>                                     | Sets the length of time that you want the CRL to remain valid.<br><br>The local CA updates and reissues the CRL each time that a user certificate is revoked or unrevoked, but if no revocation changes occur, the CRL is reissued automatically once each CRL lifetime. If you do not specify a CRL lifetime, the default time period is six hours. |
| <b>Step 3</b> | <b>crypto ca server crl issue</b><br><br><b>Example:</b><br><br><pre>hostname(config)# crypto ca server crl issue</pre> A new CRL has been issued. | Forces the issuance of a CRL at any time, which immediately updates and regenerates a current CRL to overwrite the existing CRL.<br><br><b>Note</b> Do not use this command unless the CRL file has been removed in error or has been corrupted and must be regenerated.                                                                             |

## Configuring the Server Keysize

To configure the server keysize, perform the following steps:

|               | Command                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------|-----------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>crypto ca server</b><br><br><b>Example:</b><br><br><pre>hostname (config)# crypto ca server</pre>            | Enters local CA server configuration mode. Allows you to configure and manage a local CA.                                                                                                                                                                                                                                                                                                                                                     |
| <b>Step 2</b> | <b>keysize server</b><br><br><b>Example:</b><br><br><pre>hostname (config-ca-server)# keysize server 2048</pre> | Specifies the size of the public and private keys generated at user-certificate enrollment. The keypair size options are 512, 768, 1024, 2048 bits, and the default value is 1024 bits.<br><br><b>Note</b> After you have enabled the local CA, you cannot change the local CA keysize, because all issued certificates would be invalidated. To change the local CA keysize, you must delete the current local CA and reconfigure a new one. |

## Examples

The following is sample output that shows two user certificates in the database.

```
Username: emily1
Renewal allowed until: Not Allowed
Number of times user notified: 0
PKCS12 file stored until: 12:45:52 UTC Fri Jan 4 2008
Certificates Issued:
serial: 0x71
```

```

issued:    12:45:52 UTC Thu Jan 3 2008
expired:   12:17:37 UTC Sun Dec 31 2017
status:    Not Revoked
Username:  fredl
Renewal allowed until: Not Allowed
Number of times user notified: 0
PKCS12 file stored until: 12:27:59 UTC Fri Jan 4 2008
Certificates Issued:
serial:    0x2
issued:    12:27:59 UTC Thu Jan 3 2008
expired:   12:17:37 UTC Sun Dec 31 2017
status:    Not Revoked
<--- More --->

```

## Setting Up External Local CA File Storage

You can store the local CA server configuration, users, issued certificates, and CRLs in the local CA server database either in flash memory or in an external local CA file system. To configure external local CA file storage, perform the following steps:

|               | Command                                                                                                                                                                                                                                    | Purpose                                                                                                                               |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>mount <i>name</i> <i>type</i></b><br><br><b>Example:</b><br><br>hostname (config)# mount mydata type cifs                                                                                                                               | Accesses configuration mode for the specific file system type.                                                                        |
| <b>Step 2</b> | <b>mount <i>name</i> <i>type</i> cifs</b><br><br><b>Example:</b><br><br>hostname (config-mount-cifs)# mount mydata type cifs<br>server 99.1.1.99 share myshare<br>domain frqa.ASC.com<br>username user6<br>password *****<br>status enable | Mounts a CIFS file system.<br><br><b>Note</b> Only the user who mounts a file system can unmount it with the <b>no mount</b> command. |
| <b>Step 3</b> | <b>crypto ca server</b><br><br><b>Example:</b><br><br>hostname (config)# crypto ca server                                                                                                                                                  | Enters local CA server configuration mode. Allows you to configure and manage a local CA.                                             |

|               | Command                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 4</b> | <p><b>database path</b> <i>mount-name directory-path</i></p> <p><b>Example:</b></p> <pre>hostname (config-ca-server)# database path mydata:newuser</pre> | <p>Specifies the location of <i>mydata</i>, the premounted CIFS file system to be used for the local CA server database. Establishes a path to the server and then specifies the local CA file or folder name to use for storage and retrieval.</p> <p><b>Note</b> To secure stored local CA files on an external server requires a premounted file system of file type CIFS or FTP that is username-protected and password-protected.</p> |
| <b>Step 5</b> | <p><b>write memory</b></p> <p><b>Example:</b></p> <pre>hostname (config)# write memory</pre>                                                             | <p>Saves the running configuration.</p> <p>For external local CA file storage, each time that you save the adaptive security appliance configuration, user information is saved from the adaptive security appliance to the premounted file system and file location, <i>mydata:newuser</i>.</p> <p>For flash memory storage, user information is saved automatically to the default location for the start-up configuration.</p>          |

## Examples

The following example shows the list of local CA files that appear in flash memory or in external storage:

```
hostname (config-ca-server)# dir LOCAL* //
Directory of disk0:/LOCAL*

75      -rwx   32          13:07:49 Jan 20 2007  LOCAL-CA-SERVER.ser
77      -rwx  229          13:07:49 Jan 20 2007  LOCAL-CA-SERVER.cdb
69      -rwx   0           01:09:28 Jan 20 2007  LOCAL-CA-SERVER.udb
81      -rwx  232          19:09:10 Jan 20 2007  LOCAL-CA-SERVER.crl
72      -rwx 1603          01:09:28 Jan 20 2007  LOCAL-CA-SERVER.p12

127119360 bytes total (79693824 bytes free)
```

## Downloading CRLs

To make the CRL available for HTTP download on a given interface or port, perform the following steps:

|               | Command                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server                                                | Enters local ca server configuration mode. Allows you to configure and manage a local CA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 2</b> | <b>publish-crl interface interface port portnumber</b><br><br><b>Example:</b><br>hostname (config-ca-server)# publish-crl outside 70 | <p>Opens a port on an interface to make the CRL accessible from that interface. The specified interface and port are used to listen for incoming requests for the CRL. The interface and optional port selections are as follows:</p> <ul style="list-style-type: none"> <li>• inside—Name of interface/GigabitEthernet0/1</li> <li>• management—Name of interface/Management0/0</li> <li>• outside—Name of interface/GigabitEthernet0/0</li> <li>• Port numbers can range from 1-65535. TCP port 80 is the HTTP default port number.</li> </ul> <p><b>Note</b> If you do not specify this command, the CRL is not accessible from the CDP location, because this command is required to open an interface to download the CRL file.</p> <p>The CDP URL can be configured to use the IP address of an interface, and the path of the CDP URL and the filename can also be configured (for example, http://10.10.10.100/user8/my_crl_file).</p> <p>In this case, only the interface with that IP address configured listens for CRL requests, and when a request comes in, the adaptive security appliance matches the path, /user8/my_crl_file to the configured CDP URL. When the path matches, the adaptive security appliance returns the stored CRL file.</p> <p><b>Note</b> The protocol must be HTTP, so the prefix displayed is http://.</p> |

## Storing CRLs

To establish a specific location for the automatically generated CRL of the local CA, perform the following steps:

|        | Command                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------|-------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server                                   | Enters local ca server configuration mode. Allows you to configure and manage a local CA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Step 2 | <b>cdp-url url</b><br><br><b>Example:</b><br>hostname(config-ca-server)# cdp-url<br>http://172.16.1.1/pathname/myca.crl | <p>Specifies the CDP to be included in all issued certificates. If you do not configure a specific location for the CDP, the default URL location is <code>http://hostname.domain/+CSCOCA+/asa_ca.crl</code>.</p> <p>The local CA updates and reissues the CRL each time a user certificate is revoked or unrevoked. If no revocation changes occur, the CRL is reissued once each CRL lifetime.</p> <p>If this command is set to serve the CRL directly from the local CA adaptive security appliance, see the <a href="#">“Downloading CRLs” section on page 37-36</a> for instructions about opening a port on an interface to make the CRL accessible from that interface.</p> <p>The CRL exists for other devices to validate the revocation of certificates issued by the local CA. In addition, the local CA tracks all issued certificates and status within its own certificate database. Revocation checking is performed when a validating party needs to validate a user certificate by retrieving the revocation status from an external server, which might be the CA that issued the certificate or a server designated by the CA.</p> |

## Setting Up Enrollment Parameters

To set up enrollment parameters, perform the following steps:

|               | Command                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server                              | Enters local ca server configuration mode. Allows you to configure and manage a local CA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 2</b> | <b>otp expiration timeout</b><br><br><b>Example:</b><br>hostname(config-ca-server)# otp expiration 24              | <p>Specifies the number of hours that an issued OTP for the local CA enrollment page is valid. The default expiration time is 72 hours.</p> <p><b>Note</b> The user OTP to enroll for a certificate on the enrollment website is also used as the password to unlock the PKCS12 file that includes the issued certificate and keypair for the specified user.</p>                                                                                                                                                                                                                                                          |
| <b>Step 3</b> | <b>enrollment-retrieval timeout</b><br><br><b>Example:</b><br>hostname(config-ca-server)# enrollment-retrieval 120 | <p>Specifies the number of hours an already-enrolled user can retrieve a PKCS12 enrollment file. This time period begins when the user is successfully enrolled. The default retrieval period is 24 hours. Valid values for the retrieval period range from 1 to 720 hours. The enrollment retrieval period is independent of the OTP expiration period.</p> <p>After the enrollment retrieval time expires, the user certificate and keypair are no longer available. The only way a user may receive a certificate is for the administrator to reinitialize certificate enrollment and allow a user to log in again.</p> |

## Adding and Enrolling Users

To add a user who is eligible for enrollment in the local CA database, perform the following steps:

|        | Command                                                                                                                                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto ca server user-db add</b> <i>username</i> [ <i>dn dn</i> ] [ <i>email emailaddress</i> ]<br><br><b>Example:</b><br><pre>hostname (config-ca-server)# crypto ca server user-db add user1 dn user1@example.com, Engineer, Example Company, US, email user1@example.com</pre> | <p>Adds a new user to the local CA database. Options are as follows:</p> <ul style="list-style-type: none"> <li><i>username</i>—A string of 4-64 characters, which is the simple username for the user being added. The username can be an e-mail address, which then is used to contact the user as necessary for enrollment invitations.</li> <li><i>dn</i>—The distinguished name, a global, authoritative name of an entry in the OSI Directory (X.500) (for example, cn=user1@example.com, cn=Engineer, o=Example Company, c=US).</li> <li><i>e-mail-address</i>—The e-mail address of the new user to which OTPs and notices are to be sent.</li> </ul> |
| Step 2 | <b>crypto ca server user-db allow</b> <i>user</i><br><br><b>Example:</b><br><pre>hostname (config-ca-server)# crypto ca server user-db allow user6</pre>                                                                                                                             | Provides user privileges to a newly added user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Step 3 | <b>crypto ca server user-db email-otp</b> <i>username</i><br><br><b>Example:</b><br><pre>hostname (config-ca-server)# crypto ca server user-db email-otp exampleuser1</pre>                                                                                                          | <p>Notifies a user in the local CA database to enroll and download a user certificate, which automatically e-mails the OTP to that user.</p> <p><b>Note</b> When an administrator wants to notify a user through e-mail, the administrator must specify the e-mail address in the username field or in the e-mail field when adding that user.</p>                                                                                                                                                                                                                                                                                                            |

|        | Command                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|-----------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <b>crypto ca server user-db show-otp</b><br><br><b>Example:</b><br>hostname (config-ca-server)# crypto ca server user-db show-otp | Shows the issued OTP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 5 | <b>otp expiration timeout</b><br><br><b>Example:</b><br>hostname (config-ca-server)# otp expiration 24                            | <p>Sets the enrollment time limit in hours. The default expiration time is 72 hours. The <b>otp expiration</b> command defines the amount of time that the OTP is valid for user enrollment. This time period begins when the user is allowed to enroll.</p> <p>After a user enrolls successfully within the time limit and with the correct OTP, the local CA server creates a PKCS12 file, which includes a keypair for the user and a user certificate that is based on the public key from the keypair generated and the subject-name DN specified when the user is added. The PKCS12 file contents are protected by a passphrase, the OTP. The OTP can be handled manually, or the local CA can e-mail this file to the user to download after the administrator allows enrollment.</p> <p>The PKCS12 file is saved to temporary storage with the name, <i>username.p12</i>. With the PKCS12 file in storage, the user can return within the enrollment-retrieval time period to download the PKCS12 file as many times as needed. When the time period expires, the PKCS12 file is removed from storage automatically and is no longer available to download.</p> <p><b>Note</b> If the enrollment period expires before the user retrieves the PKCS12 file that includes the user certificate, enrollment is not permitted.</p> |

## Renewing Users

To specify the timing of renewal notices, perform the following steps:

|        | Command                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|--------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server                  | Enters local CA server configuration mode. Allows you to configure and manage a local CA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 2 | <b>renewal-reminder time</b><br><br><b>Example:</b><br>hostname (config-ca-server)# renewal-reminder 7 | <p>Specifies the number of days (1-90) before the local CA certificate expires that an initial reminder to reenroll is sent to certificate owners. If a certificate expires, it becomes invalid.</p> <p>Renewal notices and the times they are e-mailed to users are variable, and can be configured by the administrator during local CA server configuration.</p> <p>Three reminders are sent. An e-mail is automatically sent to the certificate owner for each of the three reminders, provided an e-mail address is specified in the user database. If no e-mail address exists for the user, a syslog message alerts you of the renewal requirement.</p> <p>The adaptive security appliance automatically grants certificate renewal privileges to any user who holds a valid certificate that is about to expire, as long as the user still exists in the user database. Therefore, if an administrator does not want to allow a user to renew automatically, the administrator must remove the user from the database before the renewal time period.</p> |

## Restoring Users

To restore a user and a previously revoked certificate that was issued by the local CA server, perform the following steps:

|               | Command                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|---------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server                                           | Enters local ca server configuration mode. Allows you to configure and manage a local CA.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 2</b> | <b>crypto ca server unrevoke cert-serial-no</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server unrevoke 782ea09f | Restores a user and unrevokes a previously revoked certificate that was issued by the local CA server.<br><br>The local CA maintains a current CRL with serial numbers of all revoked user certificates. This list is available to external devices and can be retrieved directly from the local CA if it is configured to do so with the <b>cdp-url</b> command and the <b>publish-crl</b> command. When you revoke (or unrevoke) any current certificate by certificate serial number, the CRL automatically reflects these changes. |

## Removing Users

To delete a user from the user database by username, perform the following steps:

|               | Command                                                                                                                            | Purpose                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server                                              | Enters local ca server configuration mode. Allows you to configure and manage a local CA.                            |
| <b>Step 2</b> | <b>crypto ca server user-db remove username</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server user-db remove user1 | Removes a user from the user database and allows revocation of any valid certificates that were issued to that user. |

## Revoking Certificates

To revoke a user certificate, perform the following steps:

|        | Command                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|---------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>crypto ca server</b><br><br><b>Example:</b><br>hostname (config)# crypto ca server                                                 | Enters local ca server configuration mode. Allows you to configure and manage a local CA.                                                                                                                                                                                                                                                                                                   |
| Step 2 | <b>crypto ca server revoke cert-serial-no</b><br><br><b>Example:</b><br>hostname (config-ca-server)# crypto ca server revoke 782ea09f | Enters the certificate serial number in hexadecimal format. Marks the certificate as revoked in the certificate database on the local CA server and in the CRL, which is automatically reissued.<br><br><b>Note</b> The password is also required if the certificate for the adaptive security appliance needs to be revoked, so make sure that you record it and store it in a safe place. |

## Maintaining the Local CA Certificate Database

To maintain the local CA certificate database, make sure that you save the certificate database file, LOCAL-CA-SERVER.cdb, with the **write memory** command each time that a change to the database occurs. The local CA certificate database includes the following files:

- The LOCAL-CA-SERVER.p12 file is the archive of the local CA certificate and keypair that is generated when the local CA server is initially enabled.
- The LOCAL-CA-SERVER.crl file is the actual CRL.
- The LOCAL-CA-SERVER.ser file keeps track of the issued certificate serial numbers.

## Rolling Over Local CA Certificates

Thirty days before the local CA certificate expires, a rollover replacement certificate is generated, and a syslog message informs the administrator that it is time for local CA rollover. The new local CA certificate must be imported onto all necessary devices before the current certificate expires. If the administrator does not respond by installing the rollover certificate as the new local CA certificate, validations may fail.

The local CA certificate rolls over automatically after expiration using the same keypair. The rollover certificate is available for export in base 64 format.

### Examples

The following example shows a base 64 encoded local CA certificate:

```
MIIXlwIBAzCCF1EGCSqGSIB3DQEHAACCF0IEghc+MIIXOjCCFzYGCsQGSIB3DQEHbqCCFycwghc jAgEAMIIXHAYJKo
ZIHvCNAQcBMBsGCiqGSIb3DQEBAQMwDQQIjph4SxJyTgCAQGAghbw3v4bFy+GGG2dJnB4OLphsUM+IG3SDOiDwZG9

```

END OF CERTIFICATE

## Archiving the Local CA Server Certificate and Keypair

To archive the local CA server certificate and keypair, enter the following command:

| Command                                                                                       | Purpose                                                                                                                         |
|-----------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>copy</b>                                                                                   | Copies the local CA server certificate and keypair and all files from the adaptive security appliance using either FTP or TFTP. |
| <b>Example:</b><br><pre>hostname# copy LOCAL-CA-SERVER_0001.p12 tftp://90.1.1.22/user6/</pre> | <b>Note</b> Make sure that you back up all local CA files as often as possible.                                                 |

## Monitoring Digital Certificates

To display certificate configuration and database information, enter one or more of the following commands:

| Command                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>show crypto ca server</b>                  | Shows local CA configuration and status.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>show crypto ca server cert-db</b>          | Shows user certificates issued by the local CA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>show crypto ca server certificate</b>      | Shows local CA certificates on the console in base 64 format and the rollover certificate when available, including the rollover certificate thumbprint for verification of the new certificate during import onto other devices.                                                                                                                                                                                                                                                                                       |
| <b>show crypto ca server crt</b>              | Shows CRLs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>show crypto ca server user-db</b>          | Shows users and their status, which can be used with the following qualifiers to reduce the number of displayed records: <ul style="list-style-type: none"> <li>• <b>allowed.</b> Shows only users currently allowed to enroll.</li> <li>• <b>enrolled.</b> Shows only users that are enrolled and hold a valid certificate</li> <li>• <b>expired.</b> Shows only users holding expired certificates.</li> <li>• <b>on-hold.</b> Lists only users without a certificate and not currently allowed to enroll.</li> </ul> |
| <b>show crypto ca server user-db allowed</b>  | Shows users who are eligible to enroll.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>show crypto ca server user-db enrolled</b> | Shows enrolled users with valid certificates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>show crypto ca server user-db expired</b>  | Shows users with expired certificates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>show crypto ca server user-db on-hold</b>  | Shows users without certificates who are not allowed to enroll.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>show crypto key <i>name of key</i></b>     | Shows key pairs that you have generated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>show running-config</b>                    | Shows local CA certificate map rules.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Examples

The following example shows an RSA general-purpose key:

```
hostname/contexta(config)# show crypto key mypubkey
Key pair was generated at: 16:39:47 central Feb 10 2005
Key name: <Default-RSA-Key>
Usage: General Purpose Key
Modulus Size (bits): 1024
Key Data:

30819f30 0d06092a 864886f7 0d010101 05000381 8d003081 89028181 00ea51b7
0781848f 78bccac2 4a1b5b8d 2f3e30b4 4cae9f86 f4485207 159108c9 f5e49103

e08407dd 45d9e36e 8cc0bfef 14f9e6ac eca141e4 276d7358 f7f50d13 79020301 0001
Key pair was generated at: 16:34:54 central Feb 10 2005
```

The following example shows the local CA CRL:

```
hostname (config)# show crypto ca server crl
Certificate Revocation List:
  Issuer: cn=xx5520-1-3-2007-1
  This Update: 13:32:53 UTC Jan 4 2008
  Next Update: 13:32:53 UTC Feb 3 2008
  Number of CRL entries: 2
  CRL size: 270 bytes
Revoked Certificates:
  Serial Number: 0x6f
  Revocation Date: 12:30:01 UTC Jan 4 2008
  Serial Number: 0x47
  Revocation Date: 13:32:48 UTC Jan 4 2008
```

The following example shows one user on-hold:

```
hostname (config)# show crypto ca server user-db on-hold
username: wilma101
email: <None>
dn: <None>
allowed: <not allowed>
notified: 0
hostname (config)#
```

The following example shows output of the **show running-config** command, in which local CA certificate map rules appear:

```
crypto ca certificate map 1
  issuer-name co asc
  subject-name attr ou eq Engineering
```

# Feature History for Certificate Management

Table 37-1 lists each feature change and the platform release in which it was implemented.

**Table 37-1**      *Feature History for Certificate Management*

| Feature Name           | Platform Releases | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Certificate Management | 7.0(1)            | Digital certificates (including CA certificates, identity certificates, and code signer certificates) provide digital identification for authentication. A digital certificate includes information that identifies a device or user, such as the name, serial number, company, department, or IP address. CAs are trusted authorities that “sign” certificates to verify their authenticity, thereby guaranteeing the identity of the device or user. CAs issue digital certificates in the context of a PKI, which uses public-key or private-key encryption to ensure security. |

Table 37-1 Feature History for Certificate Management (continued)

| Feature Name           | Platform Releases | Feature Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## **PART 8**

### **Configuring Application Inspection**

## CHAPTER 38

# Getting Started With Application Layer Protocol Inspection

---

This chapter describes how to configure application layer protocol inspection. Inspection engines are required for services that embed IP addressing information in the user data packet or that open secondary channels on dynamically assigned ports. These protocols require the adaptive security appliance to do a deep packet inspection instead of passing the packet through the fast path (see the [“Stateful Inspection Overview” section on page 1-14](#) for more information about the fast path). As a result, inspection engines can affect overall throughput. Several common inspection engines are enabled on the adaptive security appliance by default, but you might need to enable others depending on your network.

This chapter includes the following sections:

- [Information about Application Layer Protocol Inspection, page 38-1](#)
- [Guidelines and Limitations, page 38-3](#)
- [Default Settings, page 38-4](#)
- [Configuring Application Layer Protocol Inspection, page 38-6](#)

## Information about Application Layer Protocol Inspection

This section includes the following topics:

- [How Inspection Engines Work, page 38-1](#)
- [When to Use Application Protocol Inspection, page 38-2](#)

## How Inspection Engines Work

As illustrated in [Figure 38-1](#), the adaptive security appliance uses three databases for its basic operation:

- Access lists—Used for authentication and authorization of connections based on specific networks, hosts, and services (TCP/UDP port numbers).
- Inspections—Contains a static, predefined set of application-level inspection functions.
- Connections (XLATE and CONN tables)—Maintains state and other information about each established connection. This information is used by the Adaptive Security Algorithm and cut-through proxy to efficiently forward traffic within established sessions.

**Figure 38-1** How Inspection Engines Work

In [Figure 38-1](#), operations are numbered in the order they occur, and are described as follows:

1. A TCP SYN packet arrives at the adaptive security appliance to establish a new connection.
2. The adaptive security appliance checks the access list database to determine if the connection is permitted.
3. The adaptive security appliance creates a new entry in the connection database (XLATE and CONN tables).
4. The adaptive security appliance checks the Inspections database to determine if the connection requires application-level inspection.
5. After the application inspection engine completes any required operations for the packet, the adaptive security appliance forwards the packet to the destination system.
6. The destination system responds to the initial request.
7. The adaptive security appliance receives the reply packet, looks up the connection in the connection database, and forwards the packet because it belongs to an established session.

The default configuration of the adaptive security appliance includes a set of application inspection entries that associate supported protocols with specific TCP or UDP port numbers and that identify any special handling required.

## When to Use Application Protocol Inspection

When a user establishes a connection, the adaptive security appliance checks the packet against access lists, creates an address translation, and creates an entry for the session in the fast path, so that further packets can bypass time-consuming checks. However, the fast path relies on predictable port numbers and does not perform address translations inside a packet.

Many protocols open secondary TCP or UDP ports. The initial session on a well-known port is used to negotiate dynamically assigned port numbers.

Other applications embed an IP address in the packet that needs to match the source address that is normally translated when it goes through the adaptive security appliance.

If you use applications like these, then you need to enable application inspection.

When you enable application inspection for a service that embeds IP addresses, the adaptive security appliance translates embedded addresses and updates any checksum or other fields that are affected by the translation.

When you enable application inspection for a service that uses dynamically assigned ports, the adaptive security appliance monitors sessions to identify the dynamic port assignments, and permits data exchange on these ports for the duration of the specific session.

## Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

### Context Mode Guidelines

Supported in single and multiple context mode.

### Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

### Failover Guidelines

State information for multimedia sessions that require inspection are not passed over the state link for stateful failover. The exception is GTP, which is replicated over the state link.

### IPv6 Guidelines

Supports IPv6 for the following inspections:

- FTP
- HTTP
- ICMP
- SIP
- SMTP
- IPSec pass-through

### Additional Guidelines and Limitations

Some inspection engines do not support PAT, NAT, outside NAT, or NAT between same security interfaces. See [“Default Settings”](#) for more information about NAT support.

For all the application inspections, the adaptive security appliance limits the number of simultaneous, active data connections to 200 connections. For example, if an FTP client opens multiple secondary connections, the FTP inspection engine allows only 200 active connections and the 201 connection is dropped and the adaptive security appliance generates a system error message.

Inspected protocols are subject to advanced TCP-state tracking, and the TCP state of these connections is not automatically replicated. While these connections are replicated to the standby unit, there is a best-effort attempt to re-establish a TCP state.

## Default Settings

By default, the configuration includes a policy that matches all default application inspection traffic and applies inspection to the traffic on all interfaces (a global policy). Default application inspection traffic includes traffic to the default ports for each protocol. You can only apply one global policy, so if you want to alter the global policy, for example, to apply inspection to non-standard ports, or to add inspections that are not enabled by default, you need to either edit the default policy or disable it and apply a new one.

Table 38-1 lists all inspections supported, the default ports used in the default class map, and the inspection engines that are on by default, shown in bold. This table also notes any NAT limitations.

**Table 38-1 Supported Application Inspection Engines**

| Application <sup>1</sup>           | Default Port                                | NAT Limitations                                               | Standards <sup>2</sup>                   | Comments                                                                                                                                                              |

| <b>SKINNY (SCCP)</b>            | TCP/2000             | No outside NAT.<br>No NAT on same security interfaces. | —                                | Does not handle TFTP uploaded Cisco IP Phone configurations under certain circumstances.                                                                                                    |
| <b>SMTP and ESMTP</b>           | TCP/25               | —                                                      | RFC 821, 1123                    | —                                                                                                                                                                                           |
| SNMP                            | UDP/161, 162         | No NAT or PAT.                                         | RFC 1155, 1157, 1212, 1213, 1215 | v.2 RFC 1902-1908; v.3 RFC 2570-2580.                                                                                                                                                       |
| <b>SQL*Net</b>                  | TCP/1521             | —                                                      | —                                | v.1 and v.2.                                                                                                                                                                                |
| <b>Sun RPC over UDP and TCP</b> | UDP/111              | No NAT or PAT.                                         | —                                | The default rule includes UDP port 111; if you want to enable Sun RPC inspection for TCP port 111, you need to create a new rule that matches TCP port 111 and performs Sun RPC inspection. |
| TFTP                            | UDP/69               | —                                                      | RFC 1350                         | Payload IP addresses are not translated.                                                                                                                                                    |
| WAAS                            | —                    | —                                                      | —                                | —                                                                                                                                                                                           |
| <b>XDCMP</b>                    | UDP/177              | No NAT or PAT.                                         | —                                | —                                                                                                                                                                                           |

1. Inspection engines that are enabled by default for the default port are in bold.
2. The adaptive security appliance is in compliance with these standards, but it does not enforce compliance on packets being inspected. For example, FTP commands are supposed to be in a particular order, but the adaptive security appliance does not enforce the order.

The default policy configuration includes the following commands:

```

class-map inspection_default
  match default-inspection-traffic
policy-map type inspect dns preset_dns_map
  parameters
    message-length maximum 512
policy-map global_policy
  class inspection_default
    inspect dns preset_dns_map
    inspect ftp
    inspect h323 h225
    inspect h323 ras
    inspect rsh
    inspect rtsp
    inspect esmtp

```

```
inspect sqlnet
inspect skinny
inspect sunrpc
inspect xdmcp
inspect sip
inspect netbios
inspect tftp
service-policy global_policy global
```

## Configuring Application Layer Protocol Inspection

This feature uses Modular Policy Framework to create a service policy. Service policies provide a consistent and flexible way to configure adaptive security appliance features. For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications. See [Chapter 30, “Configuring a Service Policy Using the Modular Policy Framework,”](#) for more information. For some applications, you can perform special actions when you enable inspection. See [Chapter 30, “Configuring a Service Policy Using the Modular Policy Framework,”](#) for more information.

Inspection is enabled by default for some applications. See the [“Default Settings”](#) section for more information. Use this section to modify your inspection policy.

### Detailed Steps

- Step 1** To identify the traffic to which you want to apply inspections, add either a Layer 3/4 class map for through traffic or a Layer 3/4 class map for management traffic. See the [“Creating a Layer 3/4 Class Map for Through Traffic”](#) section on page 30-12 and [“Creating a Layer 3/4 Class Map for Management Traffic”](#) section on page 30-15 for detailed information. The management Layer 3/4 class map can be used only with the RADIUS accounting inspection.

The default Layer 3/4 class map for through traffic is called “inspection\_default.” It matches traffic using a special **match** command, **match default-inspection-traffic**, to match the default ports for each application protocol. This traffic class (along with **match any**, which is not typically used for inspection) matches both IPv4 and IPv6 traffic for inspections that support IPv6. See the [“Guidelines and Limitations”](#) section on page 38-3 for a list of IPv6-enabled inspections.

You can specify a **match access-list** command along with the **match default-inspection-traffic** command to narrow the matched traffic to specific IP addresses. Because the **match default-inspection-traffic** command specifies the ports to match, any ports in the access list are ignored.

**Tip** We suggest that you only inspect traffic on ports on which you expect application traffic; if you inspect all traffic, for example using **match any**, the adaptive security appliance performance can be impacted.

If you want to match non-standard ports, then create a new class map for the non-standard ports. See the [“Default Settings”](#) section on page 38-4 for the standard ports for each inspection engine. You can combine multiple class maps in the same policy if desired, so you can create one class map to match certain traffic, and another to match different traffic. However, if traffic matches a class map that contains an inspection command, and then matches another class map that also has an inspection command, only the first matching class is used. For example, SNMP matches the inspection\_default class. To enable SNMP inspection, enable SNMP inspection for the default class in [Step 5](#). Do not add another class that matches SNMP.

For example, to limit inspection to traffic from 10.1.1.0 to 192.168.1.0 using the default class map, enter the following commands:

```
hostname(config)# access-list inspect extended permit ip 10.1.1.0 255.255.255.0
192.168.1.0 255.255.255.0
hostname(config)# class-map inspection_default
hostname(config-cmap)# match access-list inspect
```

View the entire class map using the following command:

```
hostname(config-cmap)# show running-config class-map inspection_default
!
class-map inspection_default
  match default-inspection-traffic
  match access-list inspect
!
```

To inspect FTP traffic on port 21 as well as 1056 (a non-standard port), create an access list that specifies the ports, and assign it to a new class map:

```
hostname(config)# access-list ftp_inspect extended permit tcp any any eq 21
hostname(config)# access-list ftp_inspect extended permit tcp any any eq 1056
hostname(config)# class-map new_inspection
hostname(config-cmap)# match access-list ftp_inspect
```

**Step 2** (Optional) Some inspection engines let you control additional parameters when you apply the inspection to the traffic. See the following sections to configure an inspection policy map for your application:

- DCERPC—See the [“Configuring a DCERPC Inspection Policy Map for Additional Inspection Control”](#) section on page 42-2
- DNS—See the [“Configuring a DNS Inspection Policy Map for Additional Inspection Control”](#) section on page 39-7
- ESMTP—See the [“Configuring an ESMTP Inspection Policy Map for Additional Inspection Control”](#) section on page 39-33
- FTP—See the [“Configuring an FTP Inspection Policy Map for Additional Inspection Control”](#) section on page 39-12.
- GTP—See the [“Configuring a GTP Inspection Policy Map for Additional Inspection Control”](#) section on page 42-4.
- H323—See the [“Configuring an H.323 Inspection Policy Map for Additional Inspection Control”](#) section on page 40-6
- HTTP—See the [“Configuring an HTTP Inspection Policy Map for Additional Inspection Control”](#) section on page 39-19.
- Instant Messaging—See the [“Configuring an Instant Messaging Inspection Policy Map for Additional Inspection Control”](#) section on page 39-24
- IP Options—See the [“Configuring an IP Options Inspection Policy Map for Additional Inspection Control”](#) section on page 39-28
- MGCP—See the [“Configuring an MGCP Inspection Policy Map for Additional Inspection Control”](#) section on page 40-13.
- NetBIOS—See the [“Configuring a NetBIOS Inspection Policy Map for Additional Inspection Control”](#) section on page 39-30
- RADIUS Accounting—See the [“Configuring a RADIUS Inspection Policy Map for Additional Inspection Control”](#) section on page 42-10

- RTSP—See the “Configuring an RTSP Inspection Policy Map for Additional Inspection Control” section on page 40-16
- SIP—See the “Configuring a SIP Inspection Policy Map for Additional Inspection Control” section on page 40-21
- Skinny—See the “Configuring a Skinny (SCCP) Inspection Policy Map for Additional Inspection Control” section on page 40-27
- SNMP—See the “Configuring an SNMP Inspection Policy Map for Additional Inspection Control” section on page 42-11.

**Step 3** To add or edit a Layer 3/4 policy map that sets the actions to take with the class map traffic, enter the following command:

```
hostname(config)# policy-map name
hostname(config-pmap)#
```

The default policy map is called “global\_policy.” This policy map includes the default inspections listed in the “Default Settings” section on page 38-4. If you want to modify the default policy (for example, to add or delete an inspection, or to identify an additional class map for your actions), then enter **global\_policy** as the name.

**Step 4** To identify the class map from [Step 1](#) to which you want to assign an action, enter the following command:

```
hostname(config-pmap)# class class_map_name
hostname(config-pmap-c)#
```

If you are editing the default policy map, it includes the inspection\_default class map. You can edit the actions for this class by entering **inspection\_default** as the name. To add an additional class map to this policy map, identify a different name. You can combine multiple class maps in the same policy if desired, so you can create one class map to match certain traffic, and another to match different traffic. However, if traffic matches a class map that contains an inspection command, and then matches another class map that also has an inspection command, only the first matching class is used. For example, SNMP matches the inspection\_default class map. To enable SNMP inspection, enable SNMP inspection for the default class in [Step 5](#). Do not add another class that matches SNMP.

**Step 5** Enable application inspection by entering the following command:

```
hostname(config-pmap-c)# inspect protocol
```

The *protocol* is one of the following values:

**Table 38-2 Protocol Keywords**

| Keywords                   | Notes                                                                                                                                                                                                |

| <b>sunrpc</b>                                | The default class map includes UDP port 111; if you want to enable Sun RPC inspection for TCP port 111, you need to create a new class map that matches TCP port 111, add the class to the policy, and then apply the <b>inspect sunrpc</b> command to that class.                                                                                                                                                                                                                               |
| <b>tftp</b>                                  | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table 38-2** Protocol Keywords

| Keywords    | Notes |
|-------------|-------|
| <b>waas</b> | —     |
| <b>xmcp</b> | —     |

**Step 6** To activate the policy map on one or more interfaces, enter the following command:

```
hostname(config)# service-policy polycymap_name {global | interface interface_name}
```

Where **global** applies the policy map to all interfaces, and **interface** applies the policy to one interface. By default, the default policy map, “global\_policy,” is applied globally. Only one global policy is allowed. You can override the global policy on an interface by applying a service policy to that interface. You can only apply one policy map to each interface.

## CHAPTER 39

# Configuring Inspection of Basic Internet Protocols

---

This chapter describes how to configure application layer protocol inspection. Inspection engines are required for services that embed IP addressing information in the user data packet or that open secondary channels on dynamically assigned ports. These protocols require the adaptive security appliance to do a deep packet inspection instead of passing the packet through the fast path. As a result, inspection engines can affect overall throughput.

Several common inspection engines are enabled on the adaptive security appliance by default, but you might need to enable others depending on your network. This chapter includes the following sections:

- [DNS Inspection, page 39-1](#)
- [FTP Inspection, page 39-11](#)
- [HTTP Inspection, page 39-18](#)
- [ICMP Inspection, page 39-23](#)
- [ICMP Error Inspection, page 39-23](#)
- [Instant Messaging Inspection, page 39-23](#)
- [IP Options Inspection, page 39-26](#)
- [IPSec Pass Through Inspection, page 39-28](#)
- [NetBIOS Inspection, page 39-29](#)
- [PPTP Inspection, page 39-31](#)
- [SMTP and Extended SMTP Inspection, page 39-32](#)
- [TFTP Inspection, page 39-35](#)

## DNS Inspection

This section describes DNS application inspection. This section includes the following topics:

- [How DNS Application Inspection Works, page 39-2](#)
- [How DNS Rewrite Works, page 39-2](#)
- [Configuring DNS Rewrite, page 39-3](#)
- [Configuring a DNS Inspection Policy Map for Additional Inspection Control, page 39-7](#)
- [Verifying and Monitoring DNS Inspection, page 39-10](#)

## How DNS Application Inspection Works

The adaptive security appliance tears down the DNS session associated with a DNS query as soon as the DNS reply is forwarded by the adaptive security appliance. The adaptive security appliance also monitors the message exchange to ensure that the ID of the DNS reply matches the ID of the DNS query.

When DNS inspection is enabled, which is the default, the adaptive security appliance performs the following additional tasks:

- Translates the DNS record based on the configuration completed using the **alias**, **static** and **nat** commands (DNS Rewrite). Translation only applies to the A-record in the DNS reply; therefore, DNS Rewrite does not affect reverse lookups, which request the PTR record.

**Note**

DNS Rewrite is not applicable for PAT because multiple PAT rules are applicable for each A-record and the PAT rule to use is ambiguous.

- Enforces the maximum DNS message length (the default is 512 bytes and the maximum length is 65535 bytes). The adaptive security appliance performs reassembly as needed to verify that the packet length is less than the maximum length configured. The adaptive security appliance drops the packet if it exceeds the maximum length.

**Note**

If you enter the **inspect dns** command without the **maximum-length** option, DNS packet size is not checked

- Enforces a domain-name length of 255 bytes and a label length of 63 bytes.
- Verifies the integrity of the domain-name referred to by the pointer if compression pointers are encountered in the DNS message.
- Checks to see if a compression pointer loop exists.

A single connection is created for multiple DNS sessions, as long as they are between the same two hosts, and the sessions have the same 5-tuple (source/destination IP address, source/destination port, and protocol). DNS identification is tracked by *app\_id*, and the idle timer for each *app\_id* runs independently.

Because the *app\_id* expires independently, a legitimate DNS response can only pass through the adaptive security appliance within a limited period of time and there is no resource build-up. However, if you enter the **show conn** command, you will see the idle timer of a DNS connection being reset by a new DNS session. This is due to the nature of the shared DNS connection and is by design.

## How DNS Rewrite Works

When DNS inspection is enabled, DNS rewrite provides full support for NAT of DNS messages originating from any interface.

If a client on an inside network requests DNS resolution of an inside address from a DNS server on an outside interface, the DNS A-record is translated correctly. If the DNS inspection engine is disabled, the A-record is not translated.

As long as DNS inspection remains enabled, you can configure DNS rewrite using the **alias**, **static**, or **nat** commands.

For details about the configuration required see the [“Configuring DNS Rewrite” section on page 39-3](#).

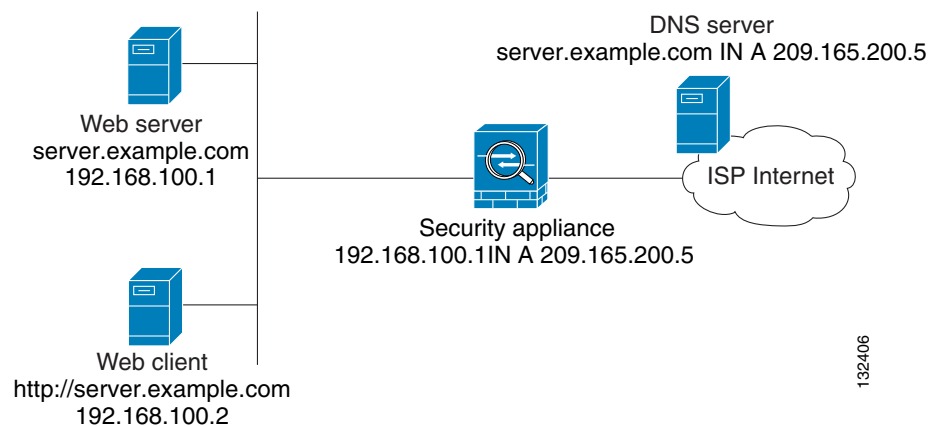

DNS Rewrite performs two functions:

- Translating a public address (the routable or “mapped” address) in a DNS reply to a private address (the “real” address) when the DNS client is on a private interface.
- Translating a private address to a public address when the DNS client is on the public interface.

In [Figure 39-1](#), the DNS server resides on the external (ISP) network. The real address of the server (192.168.100.1) has been mapped using the **static** command to the ISP-assigned address (209.165.200.5). When a web client on the inside interface attempts to access the web server with the URL `http://server.example.com`, the host running the web client sends a DNS request to the DNS server to resolve the IP address of the web server. The adaptive security appliance translates the non-routable source address in the IP header and forwards the request to the ISP network on its outside interface. When the DNS reply is returned, the adaptive security appliance applies address translation not only to the destination address, but also to the embedded IP address of the web server, which is contained in the A-record in the DNS reply. As a result, the web client on the inside network gets the correct address for connecting to the web server on the inside network.

For configuration instructions for scenarios similar to this one, see the [“Configuring DNS Rewrite with Two NAT Zones”](#) section on page 39-4.

**Figure 39-1** Translating the Address in a DNS Reply (DNS Rewrite)

DNS rewrite also works if the client making the DNS request is on a DMZ network and the DNS server is on an inside interface. For an illustration and configuration instructions for this scenario, see the [“Overview of DNS Rewrite with Three NAT Zones”](#) section on page 39-4.

## Configuring DNS Rewrite

You configure DNS rewrite using the NAT configuration.

This section includes the following topics:

- [Configuring DNS Rewrite with Two NAT Zones, page 39-4](#)
- [Overview of DNS Rewrite with Three NAT Zones, page 39-4](#)
- [Configuring DNS Rewrite with Three NAT Zones, page 39-6](#)

## Configuring DNS Rewrite with Two NAT Zones

To implement a DNS Rewrite scenario similar to the one shown in [Figure 39-1](#), perform the following steps:

- 
- Step 1** Create a static translation for the web server using the **dns** option. See [Chapter 28, “Configuring Network Object NAT.”](#)
- Step 2** Create an access list that permits traffic to the port that the web server listens to for HTTP requests.
- ```
hostname(config)# access-list acl-name extended permit tcp any host mapped-address eq port
```
- where the arguments are as follows:
- acl-name*—The name you give the access list.
- mapped-address*—The translated IP address of the web server.
- port*—The TCP port that the web server listens to for HTTP requests.
- Step 3** Apply the access list created in [Step 2](#) to the mapped interface. To do so, use the **access-group** command, as follows:
- ```
hostname(config)# access-group acl-name in interface mapped_ifc
```
- Step 4** If DNS inspection is disabled or if you want to change the maximum DNS packet length, configure DNS inspection. DNS application inspection is enabled by default with a maximum DNS packet length of 512 bytes. For configuration instructions, see the “[Configuring a DNS Inspection Policy Map for Additional Inspection Control](#)” section on [page 39-7](#).
- Step 5** On the public DNS server, add an A-record for the web server, such as:
- ```
domain-qualified-hostname. IN A mapped-address
```
- where *domain-qualified-hostname* is the hostname with a domain suffix, as in `server.example.com`. The period after the hostname is important. *mapped-address* is the translated IP address of the web server.
- 

The following example configures the adaptive security appliance for the scenario shown in [Figure 39-1](#). It assumes DNS inspection is already enabled.

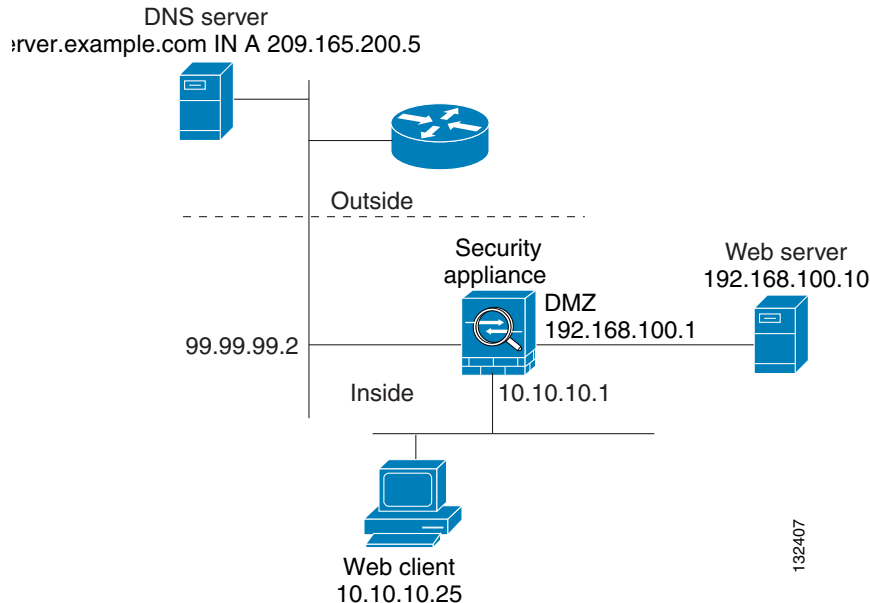

```
hostname(config)# object network obj-192.168.100.1-01
hostname(config-network-object)# host 192.168.100.1
hostname(config-network-object)# nat (inside,outside) static 209.165.200.225 dns
hostname(config)# access-list 101 permit tcp any host 209.165.200.225 eq www
hostname(config)# access-group 101 in interface outside
```

This configuration requires the following A-record on the DNS server:

```
server.example.com. IN A 209.165.200.225
```

## Overview of DNS Rewrite with Three NAT Zones

[Figure 39-2](#) provides a more complex scenario to illustrate how DNS inspection allows NAT to operate transparently with a DNS server with minimal configuration. For configuration instructions for scenarios like this one, see the “[Configuring DNS Rewrite with Three NAT Zones](#)” section on [page 39-6](#).

**Figure 39-2 DNS Rewrite with Three NAT Zones**

In [Figure 39-2](#), a web server, `server.example.com`, has the real address `192.168.100.10` on the DMZ interface of the adaptive security appliance. A web client with the IP address `10.10.10.25` is on the inside interface and a public DNS server is on the outside interface. The site NAT policies are as follows:

- The outside DNS server holds the authoritative address record for `server.example.com`.
- Hosts on the outside network can contact the web server with the domain name `server.example.com` through the outside DNS server or with the IP address `209.165.200.5`.
- Clients on the inside network can access the web server with the domain name `server.example.com` through the outside DNS server or with the IP address `192.168.100.10`.

When a host or client on any interface accesses the DMZ web server, it queries the public DNS server for the A-record of `server.example.com`. The DNS server returns the A-record showing that `server.example.com` binds to address `209.165.200.5`.

When a web client on the *outside* network attempts to access `http://server.example.com`, the sequence of events is as follows:

1. The host running the web client sends the DNS server a request for the IP address of `server.example.com`.
2. The DNS server responds with the IP address `209.165.200.225` in the reply.
3. The web client sends its HTTP request to `209.165.200.225`.
4. The packet from the outside host reaches the adaptive security appliance at the outside interface.
5. The static rule translates the address `209.165.200.225` to `192.168.100.10` and the adaptive security appliance directs the packet to the web server on the DMZ.

When a web client on the *inside* network attempts to access `http://server.example.com`, the sequence of events is as follows:

1. The host running the web client sends the DNS server a request for the IP address of `server.example.com`.
2. The DNS server responds with the IP address `209.165.200.225` in the reply.

3. The adaptive security appliance receives the DNS reply and submits it to the DNS application inspection engine.
4. The DNS application inspection engine does the following:

- a. Searches for any NAT rule to undo the translation of the embedded A-record address “[outside]:209.165.200.5”. In this example, it finds the following static configuration:

```
object network obj-192.168.100.10-01
  host 192.168.100.10
  nat (dmz,outside) static 209.165.200.5 dns
```

- b. Uses the static rule to rewrite the A-record as follows because the **dns** option is included:

```
[outside]:209.165.200.225 --> [dmz]:192.168.100.10
```

**Note** If the **dns** option were not included with the **nat** command, DNS Rewrite would not be performed and other processing for the packet continues.

- c. Searches for any NAT to translate the web server address, [dmz]:192.168.100.10, when communicating with the inside web client.

No NAT rule is applicable, so application inspection completes.

If a NAT rule (nat or static) were applicable, the **dns** option must also be specified. If the **dns** option were not specified, the A-record rewrite in step **b** would be reverted and other processing for the packet continues.

5. The adaptive security appliance sends the HTTP request to server.example.com on the DMZ interface.

## Configuring DNS Rewrite with Three NAT Zones

To enable the NAT policies for the scenario in [Figure 39-2](#), perform the following steps:

- Step 1** Create a static translation for the web server on the DMZ network using the **dns** option. See [Chapter 28](#), “Configuring Network Object NAT.”
- Step 2** Create an access list that permits traffic to the port that the web server listens to for HTTP requests.  

```
hostname(config)# access-list acl-name extended permit tcp any host mapped-address eq port
```

where the arguments are as follows:

*acl-name*—The name you give the access list.

*mapped-address*—The translated IP address of the web server.

*port*—The TCP port that the web server listens to for HTTP requests.
- Step 3** Apply the access list created in [Step 2](#) to the outside interface. To do so, use the **access-group** command, as follows:  

```
hostname(config)# access-group acl-name in interface outside
```
- Step 4** If DNS inspection is disabled or if you want to change the maximum DNS packet length, configure DNS inspection. DNS application inspection is enabled by default with a maximum DNS packet length of 512 bytes. For configuration instructions, see the “[Configuring a DNS Inspection Policy Map for Additional Inspection Control](#)” section on page 39-7.
- Step 5** On the public DNS server, add an A-record for the web server, such as:

```
domain-qualified-hostname. IN A mapped-address
```

where *domain-qualified-hostname* is the hostname with a domain suffix, as in server.example.com. The period after the hostname is important. *mapped-address* is the translated IP address of the web server.

The following example configures the adaptive security appliance for the scenario shown in Figure 39-2. It assumes DNS inspection is already enabled.

```
hostname(config)# object network obj-192.168.100.10-01
hostname(config-network-object)# host 192.168.100.10
hostname(config-network-object)# nat (dmz,outside) static 209.165.200.225 dns
hostname(config)# access-list 101 permit tcp any host 209.165.200.225 eq www
hostname(config)# access-group 101 in interface outside
```

This configuration requires the following A-record on the DNS server:

```
server.example.com. IN A 209.165.200.225
```

## Configuring a DNS Inspection Policy Map for Additional Inspection Control

DNS application inspection supports DNS message controls that provide protection against DNS spoofing and cache poisoning. User configurable rules allow filtering based on DNS header, domain name, resource record type and class. Zone transfer can be restricted between servers with this function, for example.

The Recursion Desired and Recursion Available flags in the DNS header can be masked to protect a public server from attack if that server only supports a particular internal zone. In addition, DNS randomization can be enabled to avoid spoofing and cache poisoning of servers that either do not support randomization, or utilize a weak pseudo random number generator. Limiting the domain names that can be queried also restricts the domain names which can be queried, which protects the public server further.

A configurable DNS mismatch alert can be used as notification if an excessive number of mismatching DNS responses are received, which could indicate a cache poisoning attack. In addition, a configurable check to enforce a Transaction Signature be attached to all DNS messages is also supported.

To specify actions when a message violates a parameter, create a DNS inspection policy map. You can then apply the inspection policy map when you enable DNS inspection.

To create a DNS inspection policy map, perform the following steps:

- Step 1** (Optional) Add one or more regular expressions for use in traffic matching commands according to the “[Creating a Regular Expression](#)” section on page 11-12. See the types of text you can match in the **match** commands described in [Step 3](#).
- Step 2** (Optional) Create one or more regular expression class maps to group regular expressions according to the “[Creating a Regular Expression Class Map](#)” section on page 11-15.
- Step 3** (Optional) Create a DNS inspection class map by performing the following steps.

A class map groups multiple traffic matches. Traffic must match *all* of the **match** commands to match the class map. You can alternatively identify **match** commands directly in the policy map. The difference between creating a class map and defining the traffic match directly in the inspection policy map is that the class map lets you create more complex match criteria, and you can reuse class maps.

To specify traffic that should not match the class map, use the **match not** command. For example, if the **match not** command specifies the string “example.com,” then any traffic that includes “example.com” does not match the class map.

For the traffic that you identify in this class map, you can specify actions such as drop, drop-connection, reset, mask, set the rate limit, and/or log the connection in the inspection policy map.

If you want to perform different actions for each **match** command, you should identify the traffic directly in the policy map.

- a. Create the class map by entering the following command:

```
hostname(config)# class-map type inspect dns [match-all | match-any] class_map_name
hostname(config-cmap)#
```

Where *class\_map\_name* is the name of the class map. The **match-all** keyword is the default, and specifies that traffic must match all criteria to match the class map. The **match-any** keyword specifies that the traffic matches the class map if it matches at least one of the criteria. The CLI enters class-map configuration mode, where you can enter one or more **match** commands.

- b. (Optional) To add a description to the class map, enter the following command:

```
hostname(config-cmap)# description string
```

- c. (Optional) To match a specific flag that is set in the DNS header, enter the following command:

```
hostname(config-cmap)# match [not] header-flag [eq] {f_well_known | f_value}
```

Where the *f\_well\_known* argument is the DNS flag bit. The *f\_value* argument is the 16-bit value in hex. The **eq** keyword specifies an exact match.

- d. (Optional) To match a DNS type, including Query type and RR type, enter the following command:

```
hostname(config-cmap)# match [not] dns-type {eq t_well_known | t_val} {range t_val1
t_val2}
```

Where the *t\_well\_known* argument is the DNS flag bit. The *t\_val* arguments are arbitrary values in the DNS type field (0-65535). The **range** keyword specifies a range and the **eq** keyword specifies an exact match.

- e. (Optional) To match a DNS class, enter the following command:

```
hostname(config-cmap)# match [not] dns-class {eq c_well_known | c_val} {range c_val1
c_val2}
```

Where the *c\_well\_known* argument is the DNS class. The *c\_val* arguments are arbitrary values in the DNS class field. The **range** keyword specifies a range and the **eq** keyword specifies an exact match.

- f. (Optional) To match a DNS question or resource record, enter the following command:

```
hostname(config-cmap)# match {question | {resource-record answer | authority | any}}
```

Where the **question** keyword specifies the question portion of a DNS message. The **resource-record** keyword specifies the resource record portion of a DNS message. The **answer** keyword specifies the Answer RR section. The **authority** keyword specifies the Authority RR section. The **additional** keyword specifies the Additional RR section.

- g. (Optional) To match a DNS message domain name list, enter the following command:

```
hostname(config-cmap)# match [not] domain-name {regex regex_id | regex class class_id}
```

The **regex** *regex\_name* argument is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#).

**Step 4** Create a DNS inspection policy map, enter the following command:

```
hostname(config)# policy-map type inspect dns policy_map_name
hostname(config-pmap)#
```

Where the *policy\_map\_name* is the name of the policy map. The CLI enters policy-map configuration mode.

**Step 5** (Optional) To add a description to the policy map, enter the following command:

```
hostname(config-pmap)# description string
```

**Step 6** To apply actions to matching traffic, perform the following steps.

a. Specify the traffic on which you want to perform actions using one of the following methods:

- Specify the DNS class map that you created in [Step 3](#) by entering the following command:

```
hostname(config-pmap)# class class_map_name
hostname(config-pmap-c)#
```

- Specify traffic directly in the policy map using one of the **match** commands described in [Step 3](#). If you use a **match not** command, then any traffic that does not match the criterion in the **match not** command has the action applied.

b. Specify the action you want to perform on the matching traffic by entering the following command:

```
hostname(config-pmap-c)# {[drop [send-protocol-error] |
drop-connection [send-protocol-error] | mask | reset] [log] | rate-limit message_rate}
```

Not all options are available for each **match** or **class** command. See the CLI help or the *Cisco ASA 5500 Series Command Reference* for the exact options available.

The **drop** keyword drops all packets that match.

The **send-protocol-error** keyword sends a protocol error message.

The **drop-connection** keyword drops the packet and closes the connection.

The **mask** keyword masks out the matching portion of the packet.

The **reset** keyword drops the packet, closes the connection, and sends a TCP reset to the server and/or client.

The **log** keyword, which you can use alone or with one of the other keywords, sends a system log message.

The **rate-limit** *message\_rate* argument limits the rate of messages.

You can specify multiple **class** or **match** commands in the policy map. For information about the order of **class** and **match** commands, see the “[Defining Actions in an Inspection Policy Map](#)” section on [page 31-2](#).

**Step 7** To configure parameters that affect the inspection engine, perform the following steps:

a. To enter parameters configuration mode, enter the following command:

```
hostname(config-pmap)# parameters
hostname(config-pmap-p)#
```

b. To randomize the DNS identifier for a DNS query, enter the following command:

```
hostname(config-pmap-p)# id-randomization
```

c. To enable logging for excessive DNS ID mismatches, enter the following command:

```
hostname(config-pmap-p)# id-mismatch [count number duration seconds] action log
```

Where the **count** *string* argument specifies the maximum number of mismatch instances before a system message log is sent. The **duration** *seconds* specifies the period, in seconds, to monitor.

- d. To require a TSIG resource record to be present, enter the following command:

```
hostname(config-pmap-p)# tsig enforced action {drop [log] | [log]}
```

Where the **count** *string* argument specifies the maximum number of mismatch instances before a system message log is sent. The **duration** *seconds* specifies the period, in seconds, to monitor.

The following example shows a how to define a DNS inspection policy map.

```
hostname(config)# regex domain_example "example\.com"
hostname(config)# regex domain_foo "foo\.com"

hostname(config)# ! define the domain names that the server serves
hostname(config)# class-map type inspect regex match-any my_domains
hostname(config-cmap)# match regex domain_example
hostname(config-cmap)# match regex domain_foo

hostname(config)# ! Define a DNS map for query only
hostname(config)# class-map type inspect dns match-all pub_server_map
hostname(config-cmap)# match not header-flag QR
hostname(config-cmap)# match question
hostname(config-cmap)# match not domain-name regex class my_domains

hostname(config)# policy-map type inspect dns serv_prot
hostname(config-pmap)# class pub_server_map
hostname(config-pmap-c)# drop log
hostname(config-pmap-c)# match header-flag RD
hostname(config-pmap-c)# mask log

hostname(config)# class-map dns_serv_map
hostname(config-cmap)# match default-inspection-traffic

hostname(config)# policy-map pub_policy
hostname(config-pmap)# class dns_serv_map
hostname(config-pmap-c)# inspect dns serv_prot

hostname(config)# service-policy pub_policy interface dmz
```

## Verifying and Monitoring DNS Inspection

To view information about the current DNS connections, enter the following command:

```
hostname# show conn
```

For connections using a DNS server, the source port of the connection may be replaced by the IP address of DNS server in the show conn command output.

A single connection is created for multiple DNS sessions, as long as they are between the same two hosts, and the sessions have the same 5-tuple (source/destination IP address, source/destination port, and protocol). DNS identification is tracked by app\_id, and the idle timer for each app\_id runs independently.

Because the app\_id expires independently, a legitimate DNS response can only pass through the security appliance within a limited period of time and there is no resource build-up. However, when you enter the **show conn** command, you see the idle timer of a DNS connection being reset by a new DNS session. This is due to the nature of the shared DNS connection and is by design.

To display the statistics for DNS application inspection, enter the **show service-policy** command. The following is sample output from the **show service-policy** command:

```
hostname# show service-policy
Interface outside:
  Service-policy: sample_policy
  Class-map: dns_port
    Inspect: dns maximum-length 1500, packet 0, drop 0, reset-drop 0
```

## FTP Inspection

This section describes the FTP inspection engine. This section includes the following topics:

- [FTP Inspection Overview, page 39-11](#)
- [Using the strict Option, page 39-11](#)
- [Configuring an FTP Inspection Policy Map for Additional Inspection Control, page 39-12](#)
- [Verifying and Monitoring FTP Inspection, page 39-16](#)

## FTP Inspection Overview

The FTP application inspection inspects the FTP sessions and performs four tasks:

- Prepares dynamic secondary data connection
- Tracks the FTP command-response sequence
- Generates an audit trail
- Translates the embedded IP address

FTP application inspection prepares secondary channels for FTP data transfer. Ports for these channels are negotiated through PORT or PASV commands. The channels are allocated in response to a file upload, a file download, or a directory listing event.

### Note

If you disable FTP inspection engines with the **no inspect ftp** command, outbound users can start connections only in passive mode, and all inbound FTP is disabled.

## Using the strict Option

Using the **strict** option with the **inspect ftp** command increases the security of protected networks by preventing web browsers from sending embedded commands in FTP requests.

### Note

To specify FTP commands that are not permitted to pass through the adaptive security appliance, create an FTP map according to the [“Configuring an FTP Inspection Policy Map for Additional Inspection Control” section on page 39-12](#).

After you enable the **strict** option on an interface, FTP inspection enforces the following behavior:

- An FTP command must be acknowledged before the adaptive security appliance allows a new command.

- The adaptive security appliance drops connections that send embedded commands.
- The 227 and PORT commands are checked to ensure they do not appear in an error string.

**Caution**

Using the **strict** option may cause the failure of FTP clients that are not strictly compliant with FTP RFCs.

If the **strict** option is enabled, each FTP command and response sequence is tracked for the following anomalous activity:

- Truncated command—Number of commas in the PORT and PASV reply command is checked to see if it is five. If it is not five, then the PORT command is assumed to be truncated and the TCP connection is closed.
- Incorrect command—Checks the FTP command to see if it ends with <CR><LF> characters, as required by the RFC. If it does not, the connection is closed.
- Size of RETR and STOR commands—These are checked against a fixed constant. If the size is greater, then an error message is logged and the connection is closed.
- Command spoofing—The PORT command should always be sent from the client. The TCP connection is denied if a PORT command is sent from the server.
- Reply spoofing—PASV reply command (227) should always be sent from the server. The TCP connection is denied if a PASV reply command is sent from the client. This prevents the security hole when the user executes “227 xxxxx a1, a2, a3, a4, p1, p2.”
- TCP stream editing—The adaptive security appliance closes the connection if it detects TCP stream editing.
- Invalid port negotiation—The negotiated dynamic port value is checked to see if it is less than 1024. As port numbers in the range from 1 to 1024 are reserved for well-known connections, if the negotiated port falls in this range, then the TCP connection is freed.
- Command pipelining—The number of characters present after the port numbers in the PORT and PASV reply command is cross checked with a constant value of 8. If it is more than 8, then the TCP connection is closed.
- The adaptive security appliance replaces the FTP server response to the SYST command with a series of Xs, to prevent the server from revealing its system type to FTP clients. To override this default behavior, use the **no mask-syst-reply** command in the FTP map.

## Configuring an FTP Inspection Policy Map for Additional Inspection Control

FTP command filtering and security checks are provided using strict FTP inspection for improved security and control. Protocol conformance includes packet length checks, delimiters and packet format checks, command terminator checks, and command validation.

Blocking FTP based on user values is also supported so that it is possible for FTP sites to post files for download, but restrict access to certain users. You can block FTP connections based on file type, server name, and other attributes. System message logs are generated if an FTP connection is denied after inspection.

If you want FTP inspection to allow FTP servers to reveal their system type to FTP clients, and limit the allowed FTP commands, then create and configure an FTP map. You can then apply the FTP map when you enable FTP inspection.

To create an FTP map, perform the following steps:

**Step 1** (Optional) Add one or more regular expressions for use in traffic matching commands according to the “Creating a Regular Expression” section on page 11-12. See the types of text you can match in the **match** commands described in Step 3.

**Step 2** (Optional) Create one or more regular expression class maps to group regular expressions according to the “Creating a Regular Expression Class Map” section on page 11-15.

**Step 3** (Optional) Create an FTP inspection class map by performing the following steps.

A class map groups multiple traffic matches. Traffic must match *all* of the **match** commands to match the class map. You can alternatively identify **match** commands directly in the policy map. The difference between creating a class map and defining the traffic match directly in the inspection policy map is that the class map lets you create more complex match criteria, and you can reuse class maps.

To specify traffic that should not match the class map, use the **match not** command. For example, if the **match not** command specifies the string “example.com,” then any traffic that includes “example.com” does not match the class map.

For the traffic that you identify in this class map, you can specify actions such as drop, drop-connection, reset, mask, set the rate limit, and/or log the connection in the inspection policy map.

If you want to perform different actions for each **match** command, you should identify the traffic directly in the policy map.

- a. Create the class map by entering the following command:

```
hostname(config)# class-map type inspect ftp [match-all | match-any] class_map_name
hostname(config-cmap)#
```

Where *class\_map\_name* is the name of the class map. The **match-all** keyword is the default, and specifies that traffic must match all criteria to match the class map. The **match-any** keyword specifies that the traffic matches the class map if it matches at least one of the criteria. The CLI enters class-map configuration mode, where you can enter one or more **match** commands.

- b. (Optional) To add a description to the class map, enter the following command:

```
hostname(config-cmap)# description string
```

- c. (Optional) To match a filename for FTP transfer, enter the following command:

```
hostname(config-cmap)# match [not] filename regex [regex_name | class regex_class_name]
```

Where the *regex\_name* is the regular expression you created in Step 1. The **class** *regex\_class\_name* is the regular expression class map you created in Step 2.

- d. (Optional) To match a file type for FTP transfer, enter the following command:

```
hostname(config-cmap)# match [not] filetype regex [regex_name | class regex_class_name]
```

Where the *regex\_name* is the regular expression you created in Step 1. The **class** *regex\_class\_name* is the regular expression class map you created in Step 2.

- e. (Optional) To disallow specific FTP commands, use the following command:

```
hostname(config-cmap)# match [not] request-command ftp_command [ftp_command...]
```

Where *ftp\_command* with one or more FTP commands that you want to restrict. See Table 39-1 for a list of the FTP commands that you can restrict.

**Table 39-1** FTP Map request-command deny Options

request-command deny Option	Purpose
<b>appe</b>	Disallows the command that appends to a file.
<b>cdup</b>	Disallows the command that changes to the parent directory of the current working directory.
<b>dele</b>	Disallows the command that deletes a file on the server.
<b>get</b>	Disallows the client command for retrieving a file from the server.
<b>help</b>	Disallows the command that provides help information.
<b>mkd</b>	Disallows the command that makes a directory on the server.
<b>put</b>	Disallows the client command for sending a file to the server.
<b>rmd</b>	Disallows the command that deletes a directory on the server.
<b>rnfr</b>	Disallows the command that specifies rename-from filename.
<b>rnto</b>	Disallows the command that specifies rename-to filename.
<b>site</b>	Disallows the command that are specific to the server system. Usually used for remote administration.
<b>stou</b>	Disallows the command that stores a file using a unique file name.

- f. (Optional) To match an FTP server, enter the following command:

```
hostname(config-cmap)# match [not] server regex [regex_name | class regex_class_name]
```

Where the *regex\_name* is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#).

- g. (Optional) To match an FTP username, enter the following command:

```
hostname(config-cmap)# match [not] username regex [regex_name |  
class regex_class_name]
```

Where the *regex\_name* is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#).

- h. (Optional) To match active FTP traffic commands PORT and EPRT, enter the following command:

```
hostname(config-cmap)# match [not] active-ftp
```

- i. (Optional) To match passive FTP traffic commands PASV and EPSV, enter the following command:

```
hostname(config-cmap)# match [not] passive-ftp
```

- Step 4** Create an FTP inspection policy map, enter the following command:

```
hostname(config)# policy-map type inspect ftp policy_map_name  
hostname(config-pmap)#
```

Where the *policy\_map\_name* is the name of the policy map. The CLI enters policy-map configuration mode.

- Step 5** (Optional) To add a description to the policy map, enter the following command:

```
hostname(config-pmap)# description string
```

- Step 6** To apply actions to matching traffic, perform the following steps.

- a. Specify the traffic on which you want to perform actions using one of the following methods:

- Specify the FTP class map that you created in [Step 3](#) by entering the following command:

```
hostname(config-pmap) # class class_map_name
hostname(config-pmap-c) #
```

- Specify traffic directly in the policy map using one of the **match** commands described in [Step 3](#). If you use a **match not** command, then any traffic that does not match the criterion in the **match not** command has the action applied.

- Specify the action you want to perform on the matching traffic by entering the following command:

```
hostname(config-pmap-c) # {[drop [send-protocol-error] |
drop-connection [send-protocol-error] | mask | reset] [log] | rate-limit message_rate}
```

Not all options are available for each **match** or **class** command. See the CLI help or the *Cisco ASA 5500 Series Command Reference* for the exact options available.

The **drop** keyword drops all packets that match.

The **send-protocol-error** keyword sends a protocol error message.

The **drop-connection** keyword drops the packet and closes the connection.

The **mask** keyword masks out the matching portion of the packet.

The **reset** keyword drops the packet, closes the connection, and sends a TCP reset to the server and/or client.

The **log** keyword, which you can use alone or with one of the other keywords, sends a system log message.

The **rate-limit message\_rate** argument limits the rate of messages.

You can specify multiple **class** or **match** commands in the policy map. For information about the order of **class** and **match** commands, see the “[Defining Actions in an Inspection Policy Map](#)” section on [page 31-2](#).

**Step 7** To configure parameters that affect the inspection engine, perform the following steps:

- To enter parameters configuration mode, enter the following command:

```
hostname(config-pmap) # parameters
hostname(config-pmap-p) #
```

- To mask the greeting banner from the FTP server, enter the following command:

```
hostname(config-pmap-p) # mask-banner
```

- To mask the reply to **syst** command, enter the following command:

```
hostname(config-pmap-p) # mask-syst-reply
```

Before submitting a username and password, all FTP users are presented with a greeting banner. By default, this banner includes version information useful to hackers trying to identify weaknesses in a system. The following example shows how to mask this banner:

```
hostname(config) # policy-map type inspect ftp mymap
hostname(config-pmap) # parameters
hostname(config-pmap-p) # mask-banner

hostname(config) # class-map match-all ftp-traffic
hostname(config-cmap) # match port tcp eq ftp

hostname(config) # policy-map ftp-policy
```

```
hostname(config-pmap)# class ftp-traffic
hostname(config-pmap-c)# inspect ftp strict mymap

hostname(config)# service-policy ftp-policy interface inside
```

## Verifying and Monitoring FTP Inspection

FTP application inspection generates the following log messages:

- An Audit record 303002 is generated for each file that is retrieved or uploaded.
- The FTP command is checked to see if it is RETR or STOR and the retrieve and store commands are logged.
- The username is obtained by looking up a table providing the IP address.
- The username, source IP address, destination IP address, NAT address, and the file operation are logged.
- Audit record 201005 is generated if the secondary dynamic channel preparation failed due to memory shortage.

In conjunction with NAT, the FTP application inspection translates the IP address within the application payload. This is described in detail in RFC 959.

During FTP inspection, the adaptive security appliance can drop packets silently. To see whether the adaptive security appliance has dropped any packets internally, enter the **show service-policy inspect ftp** command.

### Note

The command output does not display drop counters that are zero. The adaptive security appliance infrequently drops packets silently; therefore, the output of this command rarely displays drop counters.

Table 39-2 describes the output from the **show service-policy inspect ftp** command:

**Table 39-2 FTP Drop Counter Descriptions**

Drop Counter	Counter increments...
Back port is zero drop	If the port value is 0 when processing APPE, STOR, STOU, LIST, NLIST, RETR commands.
Can't allocate back conn drop	When an attempt to allocate a secondary data connection fails.
Can't allocate CP conn drop	When the adaptive security appliance attempts to allocate a data structure for a CP connection and the attempt fails. Check for low system memory.
Can't alloc FTP data structure drop	When the adaptive security appliance attempts to allocate a data structure for FTP inspection and the attempt fails. Check for low system memory
Can't allocate TCP proxy drop	When the adaptive security appliance attempts to allocate a data structure for a TCP proxy and the attempt fails. Check for low system memory
Can't append block drop	When the FTP packet is out of space and data cannot be added to the packet.

**Table 39-2 FTP Drop Counter Descriptions**

Drop Counter	Counter increments...
Can't PAT port drop	When the adaptive security appliance fails to configure PAT for a port.
Cmd in reply mode drop	When a command is received in REPLY mode.
Cmd match failure drop	When the adaptive security appliance encounters an internal error in regex matching. Contact Cisco TAC.
Cmd not a cmd drop	When the FTP command string contains invalid characters, such as numeric characters.
Cmd not port drop	When the adaptive security appliance expects to receive a PORT command but receives another command.
Cmd not supported drop	When the adaptive security appliance encounters an unsupported FTP command.
Cmd not supported in IPv6 drop	When an FTP command is not supported in IPv6.
Cmd not terminated drop	When the FTP command is not terminated with NL or CR.
Cmd retx unexpected drop	When a retransmitted packet is received unexpectedly.
Cmd too short drop	When the FTP command is too short.
ERPT too short drop	When the ERPT command is too short.
IDS internal error drop	When an internal error is encountered during FTP ID checks. Contact Cisco TAC.
Invalid address drop	When an invalid IP address is encountered during inspection.
Invalid EPSV format drop	When a formatting error is found in the ESPV command.
Invalid ERPT AF number drop	When the Address Family (AF) is invalid in the ERPT command.
Invalid port drop	When an invalid port is encountered during inspection.
No back port for data drop	If the packet does not contain a port when processing APPE, STOR, STOU, LIST, NLIST, RETR commands.
PORT command/reply too long drop	When the length of PORT command or passive reply is greater than 8.
Reply code invalid drop	When the reply code is invalid.
Reply length negative drop	When a reply has a negative length value.
Reply unexpected drop	If the adaptive security appliance receives a reply when a reply is not expected.
Retx cmd in cmd mode drop	When a retransmitted command is received in CMD mode.
Retx port not old port drop	When a packet is retransmitted but the port in the packet is different from the originally transmitted port.
TCP option exceeds limit drop	When the length value in a TCP option causes the length of the option to exceed the TCP header limit.
TCP option length error drop	When the length value in a TCP option is not correct.

The following is sample output from the **show service-policy inspect ftp** command:

```

hostname# show show show service-policy inspect ftp

Global policy:
Service-policy: global_policy
Class-map: inspection_default
Inspect: ftp, packet 0, drop 0, reset-drop 0
Can't alloc CP conn drop 1, Can't alloc proxy drop 2
TCP option exceeds limit drop 3, TCP option length error drop 4
Can't alloc FTP structure drop 1, Can't append block drop 2

## HTTP Inspection

This section describes the HTTP inspection engine. This section includes the following topics:

- [HTTP Inspection Overview, page 39-18](#)
- [Configuring an HTTP Inspection Policy Map for Additional Inspection Control, page 39-19](#)

## HTTP Inspection Overview

Use the HTTP inspection engine to protect against specific attacks and other threats that may be associated with HTTP traffic. HTTP inspection performs several functions:

- Enhanced HTTP inspection
- URL screening through N2H2 or Websense
- Java and ActiveX filtering

The latter two features are configured in conjunction with the **filter** command. For more information about filtering, see [Chapter 36, “Configuring Filtering Services.”](#)

The enhanced HTTP inspection feature, which is also known as an application firewall and is available when you configure an HTTP map (see [“Configuring an HTTP Inspection Policy Map for Additional Inspection Control”](#)), can help prevent attackers from using HTTP messages for circumventing network security policy. It verifies the following for all HTTP messages:

- Conformance to RFC 2616
- Use of RFC-defined methods only.
- Compliance with the additional criteria.

## Configuring an HTTP Inspection Policy Map for Additional Inspection Control

To specify actions when a message violates a parameter, create an HTTP inspection policy map. You can then apply the inspection policy map when you enable HTTP inspection.

### Note

When you enable HTTP inspection with an inspection policy map, strict HTTP inspection with the action reset and log is enabled by default. You can change the actions performed in response to inspection failure, but you cannot disable strict inspection as long as the inspection policy map remains enabled.

To create an HTTP inspection policy map, perform the following steps:

- Step 1** (Optional) Add one or more regular expressions for use in traffic matching commands according to the [“Creating a Regular Expression” section on page 11-12](#). See the types of text you can match in the **match** commands described in [Step 3](#).
- Step 2** (Optional) Create one or more regular expression class maps to group regular expressions according to the [“Creating a Regular Expression Class Map” section on page 11-15](#).
- Step 3** (Optional) Create an HTTP inspection class map by performing the following steps.

A class map groups multiple traffic matches. Traffic must match *all* of the **match** commands to match the class map. You can alternatively identify **match** commands directly in the policy map. The difference between creating a class map and defining the traffic match directly in the inspection policy map is that the class map lets you create more complex match criteria, and you can reuse class maps.

To specify traffic that should not match the class map, use the **match not** command. For example, if the **match not** command specifies the string “example.com,” then any traffic that includes “example.com” does not match the class map.

For the traffic that you identify in this class map, you can specify actions such as drop, drop-connection, reset, mask, set the rate limit, and/or log the connection in the inspection policy map.

If you want to perform different actions for each **match** command, you should identify the traffic directly in the policy map.

### Note

If you need to change a **match** command for HTTP inspection after configuring the inspection, you must remove the attached service policy by using the **no service policy** command and then reconfigure the service policy. Changing the class map by removing a **match** command causes HTTP inspection to block all HTTP traffic until you remove and reconfigure the attached service policy so that all the **match** commands are reprocessed.

- a. Create the class map by entering the following command:

```
hostname(config)# class-map type inspect http [match-all | match-any] class_map_name
hostname(config-cmap)#
```

Where *class\_map\_name* is the name of the class map. The **match-all** keyword is the default, and specifies that traffic must match all criteria to match the class map. The **match-any** keyword specifies that the traffic matches the class map if it matches at least one of the criteria. The CLI enters class-map configuration mode, where you can enter one or more **match** commands.

- b. (Optional) To add a description to the class map, enter the following command:

```
hostname(config-cmap)# description string
```

- c. (Optional) To match traffic with a content-type field in the HTTP response that does not match the accept field in the corresponding HTTP request message, enter the following command:

```
hostname(config-cmap)# match [not] req-resp content-type mismatch
```

- d. (Optional) To match text found in the HTTP request message arguments, enter the following command:

```
hostname(config-cmap)# match [not] request args regex [regex_name | class  
regex_class_name]
```

Where the *regex\_name* is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#).

- e. (Optional) To match text found in the HTTP request message body or to match traffic that exceeds the maximum HTTP request message body length, enter the following command:

```
hostname(config-cmap)# match [not] request body {regex [regex_name | class  
regex_class_name] | length gt max_bytes}
```

Where the **regex** *regex\_name* argument is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#). The **length gt** *max\_bytes* is the maximum message body length in bytes.

- f. (Optional) To match text found in the HTTP request message header, or to restrict the count or length of the header, enter the following command:

```
hostname(config-cmap)# match [not] request header {[field]  
[regex [regex_name | class regex_class_name]] |  
[length gt max_length_bytes | count gt max_count_bytes]}
```

Where the *field* is the predefined message header keyword. The **regex** *regex\_name* argument is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#). The **length gt** *max\_bytes* is the maximum message body length in bytes. The **count gt** *max\_count* is the maximum number of header fields.

- g. (Optional) To match text found in the HTTP request message method, enter the following command:

```
hostname(config-cmap)# match [not] request method {[method] |  
[regex [regex_name | class regex_class_name]]}
```

Where the *method* is the predefined message method keyword. The **regex** *regex\_name* argument is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#).

- h. (Optional) To match text found in the HTTP request message URI, enter the following command:

```
hostname(config-cmap)# match [not] request uri {regex [regex_name | class  
regex_class_name] | length gt max_bytes}
```

Where the **regex** *regex\_name* argument is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#). The **length gt** *max\_bytes* is the maximum message body length in bytes.

- i. (Optional) To match text found in the HTTP response message body, or to comment out Java applet and Active X object tags in order to filter them, enter the following command:

```
hostname(config-cmap)# match [not] response body {[active-x] | [java-applet] |  
[regex [regex_name | class regex_class_name]] | length gt max_bytes}
```

Where the **regex** *regex\_name* argument is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#). The **length gt** *max\_bytes* is the maximum message body length in bytes.

- j. (Optional) To match text found in the HTTP response message header, or to restrict the count or length of the header, enter the following command:

```
hostname(config-cmap)# match [not] response header {[field]
[regex [regex_name] | class regex_class_name]} |
[length gt max_length_bytes | count gt max_count]}
```

Where the *field* is the predefined message header keyword. The **regex** *regex\_name* argument is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#). The **length gt** *max\_bytes* is the maximum message body length in bytes. The **count gt** *max\_count* is the maximum number of header fields.

- k. (Optional) To match text found in the HTTP response message status line, enter the following command:

```
hostname(config-cmap)# match [not] response status-line {regex [regex_name] | class
regex_class_name]}
```

Where the **regex** *regex\_name* argument is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#).

- Step 4** Create an HTTP inspection policy map, enter the following command:

```
hostname(config)# policy-map type inspect http policy_map_name
hostname(config-pmap)#
```

Where the *policy\_map\_name* is the name of the policy map. The CLI enters policy-map configuration mode.

- Step 5** (Optional) To add a description to the policy map, enter the following command:

```
hostname(config-pmap)# description string
```

- Step 6** To apply actions to matching traffic, perform the following steps.

- a. Specify the traffic on which you want to perform actions using one of the following methods:

- Specify the HTTP class map that you created in [Step 3](#) by entering the following command:

```
hostname(config-pmap)# class class_map_name
hostname(config-pmap-c)#
```

- Specify traffic directly in the policy map using one of the **match** commands described in [Step 3](#). If you use a **match not** command, then any traffic that does not match the criterion in the **match not** command has the action applied.

- b. Specify the action you want to perform on the matching traffic by entering the following command:

```
hostname(config-pmap-c)# {[drop [send-protocol-error] |
drop-connection [send-protocol-error] | mask | reset] [log] | rate-limit message_rate}
```

Not all options are available for each **match** or **class** command. See the CLI help or the *Cisco ASA 5500 Series Command Reference* for the exact options available.

The **drop** keyword drops all packets that match.

The **send-protocol-error** keyword sends a protocol error message.

The **drop-connection** keyword drops the packet and closes the connection.

The **mask** keyword masks out the matching portion of the packet.

The **reset** keyword drops the packet, closes the connection, and sends a TCP reset to the server and/or client.

The **log** keyword, which you can use alone or with one of the other keywords, sends a system log message.

The **rate-limit** *message\_rate* argument limits the rate of messages.

You can specify multiple **class** or **match** commands in the policy map. For information about the order of **class** and **match** commands, see the “Defining Actions in an Inspection Policy Map” section on page 31-2.

**Step 7** To configure parameters that affect the inspection engine, perform the following steps:

- a. To enter parameters configuration mode, enter the following command:

```
hostname(config-pmap)# parameters
hostname(config-pmap-p)#
```

- b. To check for HTTP protocol violations, enter the following command:

```
hostname(config-pmap-p)# protocol-violation [action [drop-connection / reset / log]]
```

Where the **drop-connection** action closes the connection. The **reset** action closes the connection and sends a TCP reset to the client. The **log** action sends a system log message when this policy map matches traffic.

- c. To substitute a string for the server header field, enter the following command:

```
hostname(config-pmap-p)# spoof-server string
```

Where the *string* argument is the string to substitute for the server header field. Note: WebVPN streams are not subject to the **spoof-server** command.

---

The following example shows how to define an HTTP inspection policy map that will allow and log any HTTP connection that attempts to access “www\.xyz.com/\*.asp” or “www\.xyz[0-9][0-9]\.com” with methods “GET” or “PUT.” All other URL/Method combinations will be silently allowed.

```
hostname(config)# regex url1 "www\.xyz\.com/.*\.asp"
hostname(config)# regex url2 "www\.xyz[0-9][0-9]\.com"
hostname(config)# regex get "GET"
hostname(config)# regex put "PUT"

hostname(config)# class-map type regex match-any url_to_log
hostname(config-cmap)# match regex url1
hostname(config-cmap)# match regex url2
hostname(config-cmap)# exit

hostname(config)# class-map type regex match-any methods_to_log
hostname(config-cmap)# match regex get
hostname(config-cmap)# match regex put
hostname(config-cmap)# exit

hostname(config)# class-map type inspect http http_url_policy
hostname(config-cmap)# match request uri regex class url_to_log
hostname(config-cmap)# match request method regex class methods_to_log
hostname(config-cmap)# exit

hostname(config)# policy-map type inspect http http_policy
hostname(config-pmap)# class http_url_policy
hostname(config-pmap-c)# log
```

# ICMP Inspection

The ICMP inspection engine allows ICMP traffic to have a “session” so it can be inspected like TCP and UDP traffic. Without the ICMP inspection engine, we recommend that you do not allow ICMP through the adaptive security appliance in an access list. Without stateful inspection, ICMP can be used to attack your network. The ICMP inspection engine ensures that there is only one response for each request, and that the sequence number is correct.

## ICMP Error Inspection

When this feature is enabled, the adaptive security appliance creates translation sessions for intermediate hops that send ICMP error messages, based on the NAT configuration. The adaptive security appliance overwrites the packet with the translated IP addresses.

When disabled, the adaptive security appliance does not create translation sessions for intermediate nodes that generate ICMP error messages. ICMP error messages generated by the intermediate nodes between the inside host and the adaptive security appliance reach the outside host without consuming any additional NAT resource. This is undesirable when an outside host uses the traceroute command to trace the hops to the destination on the inside of the adaptive security appliance. When the adaptive security appliance does not translate the intermediate hops, all the intermediate hops appear with the mapped destination IP address.

The ICMP payload is scanned to retrieve the five-tuple from the original packet. Using the retrieved five-tuple, a lookup is performed to determine the original address of the client. The ICMP error inspection engine makes the following changes to the ICMP packet:

- In the IP Header, the mapped IP is changed to the real IP (Destination Address) and the IP checksum is modified.
- In the ICMP Header, the ICMP checksum is modified due to the changes in the ICMP packet.
- In the Payload, the following changes are made:
  - Original packet mapped IP is changed to the real IP
  - Original packet mapped port is changed to the real Port
  - Original packet IP checksum is recalculated

## Instant Messaging Inspection

This section describes the IM inspection engine. This section includes the following topics:

- [IM Inspection Overview, page 39-23](#)
- [Configuring an Instant Messaging Inspection Policy Map for Additional Inspection Control, page 39-24](#)

## IM Inspection Overview

The IM inspect engine lets you apply fine grained controls on the IM application to control the network usage and stop leakage of confidential data, propagation of worms, and other threats to the corporate network.

## Configuring an Instant Messaging Inspection Policy Map for Additional Inspection Control

To specify actions when a message violates a parameter, create an IM inspection policy map. You can then apply the inspection policy map when you enable IM inspection.

To create an IM inspection policy map, perform the following steps:

- 
- Step 1** (Optional) Add one or more regular expressions for use in traffic matching commands according to the [“Creating a Regular Expression” section on page 11-12](#). See the types of text you can match in the **match** commands described in [Step 3](#).
  - Step 2** (Optional) Create one or more regular expression class maps to group regular expressions according to the [“Creating a Regular Expression Class Map” section on page 11-15](#).
  - Step 3** (Optional) Create an IM inspection class map by performing the following steps.

A class map groups multiple traffic matches. Traffic must match *all* of the **match** commands to match the class map. You can alternatively identify **match** commands directly in the policy map. The difference between creating a class map and defining the traffic match directly in the inspection policy map is that the class map lets you create more complex match criteria, and you can reuse class maps.

To specify traffic that should not match the class map, use the **match not** command. For example, if the **match not** command specifies the string “example.com,” then any traffic that includes “example.com” does not match the class map.

For the traffic that you identify in this class map, you can specify actions such as drop-connection, reset, and/or log the connection in the inspection policy map.

If you want to perform different actions for each **match** command, you should identify the traffic directly in the policy map.

- a. Create the class map by entering the following command:

```
hostname(config)# class-map type inspect im [match-all | match-any] class_map_name
hostname(config-cmap)#
```

Where *the class\_map\_name* is the name of the class map. The **match-all** keyword is the default, and specifies that traffic must match all criteria to match the class map. The **match-any** keyword specifies that the traffic matches the class map if it matches at least one of the criteria. The CLI enters class-map configuration mode, where you can enter one or more **match** commands.

- b. (Optional) To add a description to the class map, enter the following command:

```
hostname(config-cmap)# description string
```

Where *the string* is the description of the class map (up to 200 characters).

- c. (Optional) To match traffic of a specific IM protocol, such as Yahoo or MSN, enter the following command:

```
hostname(config-cmap)# match [not] protocol {im-yahoo | im-msn}
```

- d. (Optional) To match a specific IM service, such as chat, file-transfer, webcam, voice-chat, conference, or games, enter the following command:

```
hostname(config-cmap)# match [not] service {chat | file-transfer | webcam | voice-chat
| conference | games}
```

- e. (Optional) To match the source login name of the IM message, enter the following command:

```
hostname(config-cmap)# match [not] login-name regex {class class_name | regex_name}
```

Where the **regex** *regex\_name* argument is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#).

- f. (Optional) To match the destination login name of the IM message, enter the following command:

```
hostname(config-cmap) # match [not] peer-login-name regex {class class_name | regex_name}
```

Where the **regex** *regex\_name* argument is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#).

- g. (Optional) To match the source IP address of the IM message, enter the following command:

```
hostname(config-cmap) # match [not] ip-address ip_address ip_address_mask
```

Where the *ip\_address* and the *ip\_address\_mask* is the IP address and netmask of the message source.

- h. (Optional) To match the destination IP address of the IM message, enter the following command:

```
hostname(config-cmap) # match [not] peer-ip-address ip_address ip_address_mask
```

Where the *ip\_address* and the *ip\_address\_mask* is the IP address and netmask of the message destination.

- i. (Optional) To match the version of the IM message, enter the following command:

```
hostname(config-cmap) # match [not] version regex {class class_name | regex_name}
```

Where the **regex** *regex\_name* argument is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#).

- j. (Optional) To match the filename of the IM message, enter the following command:

```
hostname(config-cmap) # match [not] filename regex {class class_name | regex_name}
```

Where the **regex** *regex\_name* argument is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#).

**Note** Not supported using MSN IM protocol.

- Step 4** Create an IM inspection policy map, enter the following command:

```
hostname(config) # policy-map type inspect im policy_map_name
hostname(config-pmap) #
```

Where the *policy\_map\_name* is the name of the policy map. The CLI enters policy-map configuration mode.

- Step 5** (Optional) To add a description to the policy map, enter the following command:

```
hostname(config-pmap) # description string
```

- Step 6** Specify the traffic on which you want to perform actions using one of the following methods:

- Specify the IM class map that you created in [Step 3](#) by entering the following command:

```
hostname(config-pmap) # class class_map_name
hostname(config-pmap-c) #
```

- Specify traffic directly in the policy map using one of the **match** commands described in [Step 3](#). If you use a **match not** command, then any traffic that does not match the criterion in the **match not** command has the action applied.

You can specify multiple **class** or **match** commands in the policy map. For information about the order of **class** and **match** commands, see the [“Defining Actions in an Inspection Policy Map” section on page 31-2](#).

**Step 7** Specify the action you want to perform on the matching traffic by entering the following command:

```
hostname(config-pmap-c) # {drop-connection | reset | log}
```

Where the **drop-connection** action closes the connection. The **reset** action closes the connection and sends a TCP reset to the client. The **log** action sends a system log message when this policy map matches traffic.

The following example shows how to define an IM inspection policy map.

```
hostname(config)# regex loginname1 "ying@yahoo.com"
hostname(config)# regex loginname2 "Kevin@yahoo.com"
hostname(config)# regex loginname3 "rahul@yahoo.com"
hostname(config)# regex loginname4 "darshant@yahoo.com"
hostname(config)# regex yahoo_version_regex "1\\.0"
hostname(config)# regex gif_files "\\.*\\.gif"
hostname(config)# regex exe_files "\\.*\\.exe"

hostname(config)# class-map type regex match-any yahoo_src_login_name_regex
hostname(config-cmap)# match regex loginname1
hostname(config-cmap)# match regex loginname2

hostname(config)# class-map type regex match-any yahoo_dst_login_name_regex
hostname(config-cmap)# match regex loginname3
hostname(config-cmap)# match regex loginname4

hostname(config)# class-map type inspect im match-any yahoo_file_block_list
hostname(config-cmap)# match filename regex gif_files
hostname(config-cmap)# match filename regex exe_files

hostname(config)# class-map type inspect im match-all yahoo_im_policy
hostname(config-cmap)# match login-name regex class yahoo_src_login_name_regex
hostname(config-cmap)# match peer-login-name regex class yahoo_dst_login_name_regex

hostname(config)# class-map type inspect im match-all yahoo_im_policy2
hostname(config-cmap)# match version regex yahoo_version_regex

hostname(config)# class-map im_inspect_class_map
hostname(config-cmap)# match default-inspection-traffic

hostname(config)# policy-map type inspect im im_policy_all
hostname(config-pmap)# class yahoo_file_block_list
hostname(config-pmap-c)# match service file-transfer
hostname(config-pmap)# class yahoo_im_policy
hostname(config-pmap-c)# drop-connection
hostname(config-pmap)# class yahoo_im_policy2
hostname(config-pmap-c)# reset
hostname(config)# policy-map global_policy_name
hostname(config-pmap)# class im_inspect_class_map
hostname(config-pmap-c)# inspect im im_policy_all
```

## IP Options Inspection

This section describes the IP Options inspection engine. This section includes the following topics:

- [IP Options Inspection Overview, page 39-27](#)
- [Configuring an IP Options Inspection Policy Map for Additional Inspection Control, page 39-28](#)

## IP Options Inspection Overview

Each IP packet contains an IP header with the Options field. The Options field, commonly referred to as IP Options, provide for control functions that are required in some situations but unnecessary for most common communications. In particular, IP Options include provisions for time stamps, security, and special routing. Use of IP Options is optional, and the field can contain zero, one, or more options.

You can configure IP Options inspection to control which IP packets with specific IP options are allowed through the adaptive security appliance. Configuring this inspection instructs the adaptive security appliance to allow a packet to pass or to clear the specified IP options and then allow the packet to pass.

IP Options inspection can check for the following three IP options in a packet:

- End of Options List (EOOL) or IP Option 0—This option, which contains just a single zero byte, appears at the end of all options to mark the end of a list of options. This might not coincide with the end of the header according to the header length.
- No Operation (NOP) or IP Option 1—The Options field in the IP header can contain zero, one, or more options, which makes the total length of the field variable. However, the IP header must be a multiple of 32 bits. If the number of bits of all options is not a multiple of 32 bits, the NOP option is used as “internal padding” to align the options on a 32-bit boundary.
- Router Alert (RTRALT) or IP Option 20—This option notifies transit routers to inspect the contents of the packet even when the packet is not destined for that router. This inspection is valuable when implementing RSVP and similar protocols require relatively complex processing from the routers along the packets delivery path.

### Note

IP Options inspection is included by default in the global inspection policy. Therefore, the adaptive security appliance allows RSVP traffic that contains packets with the Router Alert option (option 20) when the adaptive security appliance is in routed mode.

Dropping RSVP packets containing the Router Alert option can cause problems in VoIP implementations.

When you configure the adaptive security appliance to clear the Router Alert option from IP headers, the IP header changes in the following ways:

- The Options field is padded so that the field ends on a 32 bit boundary.
- Internet header length (IHL) changes.
- The total length of the packet changes.
- The checksum is recomputed.

If an IP header contains additional options other than EOOL, NOP, or RTRALT, regardless of whether the adaptive security appliance is configured to allow these options, the adaptive security appliance will drop the packet.

## Configuring an IP Options Inspection Policy Map for Additional Inspection Control

**Step 1** To create an IP Options inspection policy map, enter the following command:

```
hostname(config)# policy-map type inspect ip-options policy_map_name
hostname(config-pmap)#
```

Where the *policy\_map\_name* is the name of the policy map. The CLI enters policy-map configuration mode.

**Step 2** (Optional) To add a description to the policy map, enter the following command:

```
hostname(config-pmap)# description string
```

**Step 3** To configure parameters that affect the inspection engine, perform the following steps:

a. To enter parameters configuration mode, enter the following command:

```
hostname(config-pmap)# parameters
hostname(config-pmap-p)#
```

b. To allow or clear packets with the End of Options List (EOOL) option, enter the following command:

```
hostname(config-pmap-p)# eoool action {allow | clear}
```

This option, which contains just a single zero byte, appears at the end of all options to mark the end of a list of options. This might not coincide with the end of the header according to the header length.

c. To allow or clear packets with the No Operation (NOP) option, enter the following command:

```
hostname(config-pmap-p)# nop action {allow | clear}
```

The Options field in the IP header can contain zero, one, or more options, which makes the total length of the field variable. However, the IP header must be a multiple of 32 bits. If the number of bits of all options is not a multiple of 32 bits, the NOP option is used as “internal padding” to align the options on a 32-bit boundary.

d. To allow or clear packets with the Router Alert (RTRALT) option, enter the following command:

```
hostname(config-pmap-p)# router-alert action {allow | clear}
```

This option notifies transit routers to inspect the contents of the packet even when the packet is not destined for that router. This inspection is valuable when implementing RSVP and similar protocols require relatively complex processing from the routers along the packets delivery path.

### Note

Enter the **clear** command to clear the IP option from the packet before allowing the packet through the adaptive security appliance.

## IPSec Pass Through Inspection

This section describes the IPSec Pass Through inspection engine. This section includes the following topics:

- [IPSec Pass Through Inspection Overview, page 39-29](#)
- [“Example for Defining an IPSec Pass Through Parameter Map” section on page 39-29](#)

## IPSec Pass Through Inspection Overview

Internet Protocol Security (IPSec) is a protocol suite for securing IP communications by authenticating and encrypting each IP packet of a data stream. IPSec also includes protocols for establishing mutual authentication between agents at the beginning of the session and negotiation of cryptographic keys to be used during the session. IPSec can be used to protect data flows between a pair of hosts (for example, computer users or servers), between a pair of security gateways (such as routers or firewalls), or between a security gateway and a host.

IPSec Pass Through application inspection provides convenient traversal of ESP (IP protocol 50) and AH (IP protocol 51) traffic associated with an IKE UDP port 500 connection. It avoids lengthy access list configuration to permit ESP and AH traffic and also provides security using timeout and max connections.

Specify IPSec Pass Through inspection parameters to identify a specific map to use for defining the parameters for the inspection. Configure a policy map for Specify IPSec Pass Through inspection to access the parameters configuration, which lets you specify the restrictions for ESP or AH traffic. You can set the per client max connections and the idle timeout in parameters configuration.

NAT and non-NAT traffic is permitted. However, PAT is not supported.

## Example for Defining an IPSec Pass Through Parameter Map

The following example shows how to use access lists to identify IKE traffic, define an IPSec Pass Through parameter map, define a policy, and apply the policy to the outside interface:

```
hostname(config)# access-list ipsecpassthruacl permit udp any any eq 500
hostname(config)# class-map ipsecpassthru-traffic
hostname(config-cmap)# match access-list ipsecpassthruacl
hostname(config)# policy-map type inspect ipsec-pass-thru iptmap
hostname(config-pmap)# parameters
hostname(config-pmap-p)# esp per-client-max 10 timeout 0:11:00
hostname(config-pmap-p)# ah per-client-max 5 timeout 0:06:00
hostname(config)# policy-map inspection_policy
hostname(config-pmap)# class ipsecpassthru-traffic
hostname(config-pmap-c)# inspect ipsec-pass-thru iptmap
hostname(config)# service-policy inspection_policy interface outside
```

## NetBIOS Inspection

This section describes the IM inspection engine. This section includes the following topics:

- [NetBIOS Inspection Overview, page 39-30](#)
- [Configuring a NetBIOS Inspection Policy Map for Additional Inspection Control, page 39-30](#)

## NetBIOS Inspection Overview

NetBIOS inspection is enabled by default. The NetBios inspection engine translates IP addresses in the NetBios name service (NBNS) packets according to the adaptive security appliance NAT configuration.

## Configuring a NetBIOS Inspection Policy Map for Additional Inspection Control

To specify actions when a message violates a parameter, create a NETBIOS inspection policy map. You can then apply the inspection policy map when you enable NETBIOS inspection.

To create a NETBIOS inspection policy map, perform the following steps:

**Step 1** (Optional) Add one or more regular expressions for use in traffic matching commands according to the “[Creating a Regular Expression](#)” section on page 11-12. See the types of text you can match in the **match** commands described in [Step 3](#).

**Step 2** (Optional) Create one or more regular expression class maps to group regular expressions according to the “[Creating a Regular Expression Class Map](#)” section on page 11-15.

**Step 3** Create a NetBIOS inspection policy map, enter the following command:

```
hostname(config)# policy-map type inspect netbios policy_map_name
hostname(config-pmap)#
```

Where the *policy\_map\_name* is the name of the policy map. The CLI enters policy-map configuration mode.

**Step 4** (Optional) To add a description to the policy map, enter the following command:

```
hostname(config-pmap)# description string
```

**Step 5** To apply actions to matching traffic, perform the following steps.

a. Specify the traffic on which you want to perform actions using one of the following methods:

- Specify the NetBIOS class map that you created in [Step 3](#) by entering the following command:

```
hostname(config-pmap)# class class_map_name
hostname(config-pmap-c)#
```

- Specify traffic directly in the policy map using one of the **match** commands described in [Step 3](#). If you use a **match not** command, then any traffic that does not match the criterion in the **match not** command has the action applied.

b. Specify the action you want to perform on the matching traffic by entering the following command:

```
hostname(config-pmap-c)# {[drop [send-protocol-error] |
drop-connection [send-protocol-error] | mask | reset] [log] | rate-limit message_rate}
```

Not all options are available for each **match** or **class** command. See the CLI help or the *Cisco ASA 5500 Series Command Reference* for the exact options available.

The **drop** keyword drops all packets that match.

The **send-protocol-error** keyword sends a protocol error message.

The **drop-connection** keyword drops the packet and closes the connection.

The **mask** keyword masks out the matching portion of the packet.

The **reset** keyword drops the packet, closes the connection, and sends a TCP reset to the server and/or client.

The **log** keyword, which you can use alone or with one of the other keywords, sends a system log message.

The **rate-limit** *message\_rate* argument limits the rate of messages.

You can specify multiple **class** or **match** commands in the policy map. For information about the order of **class** and **match** commands, see the “Defining Actions in an Inspection Policy Map” section on page 31-2.

**Step 6** To configure parameters that affect the inspection engine, perform the following steps:

- a. To enter parameters configuration mode, enter the following command:

```
hostname(config-pmap)# parameters
hostname(config-pmap-p)#
```

- b. To check for NETBIOS protocol violations, enter the following command:

```
hostname(config-pmap-p)# protocol-violation [action [drop-connection / reset / log]]
```

Where the **drop-connection** action closes the connection. The **reset** action closes the connection and sends a TCP reset to the client. The **log** action sends a system log message when this policy map matches traffic.

The following example shows how to define a NETBIOS inspection policy map.

```
hostname(config)# policy-map type inspect netbios netbios_map
hostname(config-pmap)# protocol-violation drop log

hostname(config)# policy-map netbios_policy
hostname(config-pmap)# class inspection_default
hostname(config-pmap-c)# inspect netbios netbios_map
```

## PPTP Inspection

PPTP is a protocol for tunneling PPP traffic. A PPTP session is composed of one TCP channel and usually two PPTP GRE tunnels. The TCP channel is the control channel used for negotiating and managing the PPTP GRE tunnels. The GRE tunnels carries PPP sessions between the two hosts.

When enabled, PPTP application inspection inspects PPTP protocol packets and dynamically creates the GRE connections and xlates necessary to permit PPTP traffic. Only Version 1, as defined in RFC 2637, is supported.

PAT is only performed for the modified version of GRE [RFC 2637] when negotiated over the PPTP TCP control channel. Port Address Translation is *not* performed for the unmodified version of GRE [RFC 1701, RFC 1702].

Specifically, the adaptive security appliance inspects the PPTP version announcements and the outgoing call request/response sequence. Only PPTP Version 1, as defined in RFC 2637, is inspected. Further inspection on the TCP control channel is disabled if the version announced by either side is not Version 1. In addition, the outgoing-call request and reply sequence are tracked. Connections and xlates are dynamic allocated as necessary to permit subsequent secondary GRE data traffic.

The PPTP inspection engine must be enabled for PPTP traffic to be translated by PAT. Additionally, PAT is only performed for a modified version of GRE (RFC2637) and only if it is negotiated over the PPTP TCP control channel. PAT is not performed for the unmodified version of GRE (RFC 1701 and RFC 1702).

As described in RFC 2637, the PPTP protocol is mainly used for the tunneling of PPP sessions initiated from a modem bank PAC (PPTP Access Concentrator) to the headend PNS (PPTP Network Server). When used this way, the PAC is the remote client and the PNS is the server.

However, when used for VPN by Windows, the interaction is inverted. The PNS is a remote single-user PC that initiates connection to the head-end PAC to gain access to a central network.

## SMTP and Extended SMTP Inspection

This section describes the IM inspection engine. This section includes the following topics:

- [SMTP and ESMTP Inspection Overview, page 39-32](#)
- [Configuring an ESMTP Inspection Policy Map for Additional Inspection Control, page 39-33](#)

### SMTP and ESMTP Inspection Overview

ESMTP application inspection provides improved protection against SMTP-based attacks by restricting the types of SMTP commands that can pass through the adaptive security appliance and by adding monitoring capabilities.

ESMTP is an enhancement to the SMTP protocol and is similar in most respects to SMTP. For convenience, the term SMTP is used in this document to refer to both SMTP and ESMTP. The application inspection process for extended SMTP is similar to SMTP application inspection and includes support for SMTP sessions. Most commands used in an extended SMTP session are the same as those used in an SMTP session but an ESMTP session is considerably faster and offers more options related to reliability and security, such as delivery status notification.

Extended SMTP application inspection adds support for these extended SMTP commands, including AUTH, EHLO, ETRN, HELP, SAML, SEND, SOML, STARTTLS, and VRFY. Along with the support for seven RFC 821 commands (DATA, HELO, MAIL, NOOP, QUIT, RCPT, RSET), the adaptive security appliance supports a total of fifteen SMTP commands.

Other extended SMTP commands, such as ATRN, ONEX, VERB, CHUNKING, and private extensions are not supported. Unsupported commands are translated into Xs, which are rejected by the internal server. This results in a message such as “500 Command unknown: ‘XXX’.” Incomplete commands are discarded.

The ESMTP inspection engine changes the characters in the server SMTP banner to asterisks except for the “2”, “0”, “O” characters. Carriage return (CR) and linefeed (LF) characters are ignored.

With SMTP inspection enabled, a Telnet session used for interactive SMTP may hang if the following rules are not observed: SMTP commands must be at least four characters in length; must be terminated with carriage return and line feed; and must wait for a response before issuing the next reply.

An SMTP server responds to client requests with numeric reply codes and optional human-readable strings. SMTP application inspection controls and reduces the commands that the user can use as well as the messages that the server returns. SMTP inspection performs three primary tasks:

- Restricts SMTP requests to seven basic SMTP commands and eight extended commands.
- Monitors the SMTP command-response sequence.
- Generates an audit trail—Audit record 108002 is generated when invalid character embedded in the mail address is replaced. For more information, see RFC 821.

SMTP inspection monitors the command and response sequence for the following anomalous signatures:

- Truncated commands.
- Incorrect command termination (not terminated with <CR><LR>).
- The MAIL and RCPT commands specify who are the sender and the receiver of the mail. Mail addresses are scanned for strange characters. The pipeline character (|) is deleted (changed to a blank space) and "<" , ">" are only allowed if they are used to define a mail address (">" must be preceded by "<").
- Unexpected transition by the SMTP server.
- For unknown commands, the adaptive security appliance changes all the characters in the packet to X. In this case, the server generates an error code to the client. Because of the change in the packet, the TCP checksum has to be recalculated or adjusted.
- TCP stream editing.
- Command pipelining.

## Configuring an ESMTP Inspection Policy Map for Additional Inspection Control

ESMTP inspection detects attacks, including spam, phishing, malformed message attacks, buffer overflow/underflow attacks. It also provides support for application security and protocol conformance, which enforce the sanity of the ESMTP messages as well as detect several attacks, block senders/receivers, and block mail relay.

To specify actions when a message violates a parameter, create an ESMTP inspection policy map. You can then apply the inspection policy map when you enable ESMTP inspection.

To create an ESMTP inspection policy map, perform the following steps:

**Step 1** (Optional) Add one or more regular expressions for use in traffic matching commands according to the [“Creating a Regular Expression”](#) section on page 11-12. See the types of text you can match in the **match** commands described in [Step 3](#).

**Step 2** (Optional) Create one or more regular expression class maps to group regular expressions according to the [“Creating a Regular Expression Class Map”](#) section on page 11-15.

**Step 3** Create an ESMTP inspection policy map, enter the following command:

```
hostname(config)# policy-map type inspect esmtp policy_map_name
hostname(config-pmap)#
```

Where the *policy\_map\_name* is the name of the policy map. The CLI enters policy-map configuration mode.

**Step 4** (Optional) To add a description to the policy map, enter the following command:

```
hostname(config-pmap)# description string
```

**Step 5** To apply actions to matching traffic, perform the following steps.

a. Specify the traffic on which you want to perform actions using one of the following methods:

- Specify the ESMTP class map that you created in [Step 3](#) by entering the following command:

```
hostname(config-pmap)# class class_map_name
hostname(config-pmap-c)#
```

- Specify traffic directly in the policy map using one of the **match** commands described in [Step 3](#). If you use a **match not** command, then any traffic that does not match the criterion in the **match not** command has the action applied.

- b. Specify the action you want to perform on the matching traffic by entering the following command:

```
hostname(config-pmap-c)# {[drop [send-protocol-error] |
drop-connection [send-protocol-error] | mask | reset] [log] | rate-limit message_rate}
```

Not all options are available for each **match** or **class** command. See the CLI help or the *Cisco ASA 5500 Series Command Reference* for the exact options available.

The **drop** keyword drops all packets that match.

The **send-protocol-error** keyword sends a protocol error message.

The **drop-connection** keyword drops the packet and closes the connection.

The **mask** keyword masks out the matching portion of the packet.

The **reset** keyword drops the packet, closes the connection, and sends a TCP reset to the server and/or client.

The **log** keyword, which you can use alone or with one of the other keywords, sends a system log message.

The **rate-limit message\_rate** argument limits the rate of messages.

You can specify multiple **class** or **match** commands in the policy map. For information about the order of **class** and **match** commands, see the [“Defining Actions in an Inspection Policy Map”](#) section on page 31-2.

- Step 6** To configure parameters that affect the inspection engine, perform the following steps:

- a. To enter parameters configuration mode, enter the following command:

```
hostname(config-pmap)# parameters
hostname(config-pmap-p)#
```

- b. To configure a local domain name, enter the following command:

```
hostname(config-pmap-p)# mail-relay domain-name action [drop-connection / log]]
```

Where the **drop-connection** action closes the connection. The **log** action sends a system log message when this policy map matches traffic.

- c. To enforce banner obfuscation, enter the following command:

```
hostname(config-pmap-p)# mask-banner
```

---

The following example shows how to define an ESMTP inspection policy map.

```
hostname(config)# regex user1 "user1@cisco.com"
hostname(config)# regex user2 "user2@cisco.com"
hostname(config)# regex user3 "user3@cisco.com"
hostname(config)# class-map type regex senders_black_list
hostname(config-cmap)# description "Regular expressions to filter out undesired senders"
hostname(config-cmap)# match regex user1
hostname(config-cmap)# match regex user2
hostname(config-cmap)# match regex user3

hostname(config)# policy-map type inspect esmtp advanced_esmtp_map
hostname(config-pmap)# match sender-address regex class senders_black_list
hostname(config-pmap-c)# drop-connection log

hostname(config)# policy-map outside_policy
hostname(config-pmap)# class inspection_default
hostname(config-pmap-c)# inspect esmtp advanced_esmtp_map
```

```
hostname(config)# service-policy outside_policy interface outside
```

## TFTP Inspection

TFTP inspection is enabled by default.

TFTP, described in RFC 1350, is a simple protocol to read and write files between a TFTP server and client.

The adaptive security appliance inspects TFTP traffic and dynamically creates connections and translations, if necessary, to permit file transfer between a TFTP client and server. Specifically, the inspection engine inspects TFTP read request (RRQ), write request (WRQ), and error notification (ERROR).

A dynamic secondary channel and a PAT translation, if necessary, are allocated on a reception of a valid read (RRQ) or write (WRQ) request. This secondary channel is subsequently used by TFTP for file transfer or error notification.

Only the TFTP server can initiate traffic over the secondary channel, and at most one incomplete secondary channel can exist between the TFTP client and server. An error notification from the server closes the secondary channel.

TFTP inspection must be enabled if static PAT is used to redirect TFTP traffic.

## CHAPTER 40

# Configuring Inspection for Voice and Video Protocols

---

This chapter describes how to configure application layer protocol inspection. Inspection engines are required for services that embed IP addressing information in the user data packet or that open secondary channels on dynamically assigned ports. These protocols require the adaptive security appliance to do a deep packet inspection instead of passing the packet through the fast path. As a result, inspection engines can affect overall throughput.

Several common inspection engines are enabled on the adaptive security appliance by default, but you might need to enable others depending on your network. This chapter includes the following sections:

- [CTIQBE Inspection, page 40-1](#)
- [H.323 Inspection, page 40-3](#)
- [MGCP Inspection, page 40-11](#)
- [RTSP Inspection, page 40-15](#)
- [SIP Inspection, page 40-19](#)
- [Skinny \(SCCP\) Inspection, page 40-25](#)

## CTIQBE Inspection

This section describes CTIQBE application inspection. This section includes the following topics:

- [CTIQBE Inspection Overview, page 40-1](#)
- [Limitations and Restrictions, page 40-2](#)
- [Verifying and Monitoring CTIQBE Inspection, page 40-2](#)

## CTIQBE Inspection Overview

CTIQBE protocol inspection supports NAT, PAT, and bidirectional NAT. This enables Cisco IP SoftPhone and other Cisco TAPI/JTAPI applications to work successfully with Cisco CallManager for call setup across the adaptive security appliance.

TAPI and JTAPI are used by many Cisco VoIP applications. CTIQBE is used by Cisco TSP to communicate with Cisco CallManager.

## Limitations and Restrictions

The following summarizes limitations that apply when using CTIQBE application inspection:

- CTIQBE application inspection does not support configurations with the **alias** command.
- Stateful failover of CTIQBE calls is not supported.
- Entering the **debug ctiqbe** command may delay message transmission, which may have a performance impact in a real-time environment. When you enable this debugging or logging and Cisco IP SoftPhone seems unable to complete call setup through the adaptive security appliance, increase the timeout values in the Cisco TSP settings on the system running Cisco IP SoftPhone.

The following summarizes special considerations when using CTIQBE application inspection in specific scenarios:

- If two Cisco IP SoftPhones are registered with different Cisco CallManagers, which are connected to different interfaces of the adaptive security appliance, calls between these two phones fails.
- When Cisco CallManager is located on the higher security interface compared to Cisco IP SoftPhones, if NAT or outside NAT is required for the Cisco CallManager IP address, the mapping must be static as Cisco IP SoftPhone requires the Cisco CallManager IP address to be specified explicitly in its Cisco TSP configuration on the PC.
- When using PAT or Outside PAT, if the Cisco CallManager IP address is to be translated, its TCP port 2748 must be statically mapped to the same port of the PAT (interface) address for Cisco IP SoftPhone registrations to succeed. The CTIQBE listening port (TCP 2748) is fixed and is not user-configurable on Cisco CallManager, Cisco IP SoftPhone, or Cisco TSP.

## Verifying and Monitoring CTIQBE Inspection

The **show ctiqbe** command displays information regarding the CTIQBE sessions established across the adaptive security appliance. It shows information about the media connections allocated by the CTIQBE inspection engine.

The following is sample output from the **show ctiqbe** command under the following conditions. There is only one active CTIQBE session setup across the adaptive security appliance. It is established between an internal CTI device (for example, a Cisco IP SoftPhone) at local address 10.0.0.99 and an external Cisco CallManager at 172.29.1.77, where TCP port 2748 is the Cisco CallManager. The heartbeat interval for the session is 120 seconds.

```
hostname# # show ctiqbe

Total: 1
      LOCAL          FOREIGN          STATE    HEARTBEAT
-----
1      10.0.0.99/1117  172.29.1.77/2748          1         120
-----
RTP/RTCP: PAT xlates: mapped to 172.29.1.99(1028 - 1029)
-----
MEDIA: Device ID 27      Call ID 0
      Foreign 172.29.1.99      (1028 - 1029)
      Local   172.29.1.88      (26822 - 26823)
-----
```

The CTI device has already registered with the CallManager. The device internal address and RTP listening port is PATed to 172.29.1.99 UDP port 1028. Its RTCP listening port is PATed to UDP 1029.

The line beginning with `RTP/RTCP: PAT xlates:` appears only if an internal CTI device has registered with an external CallManager and the CTI device address and ports are PATED to that external interface. This line does not appear if the CallManager is located on an internal interface, or if the internal CTI device address and ports are translated to the same external interface that is used by the CallManager.

The output indicates a call has been established between this CTI device and another phone at 172.29.1.88. The RTP and RTCP listening ports of the other phone are UDP 26822 and 26823. The other phone locates on the same interface as the CallManager because the adaptive security appliance does not maintain a CTIQBE session record associated with the second phone and CallManager. The active call leg on the CTI device side can be identified with Device ID 27 and Call ID 0.

The following is sample output from the `show xlate debug` command for these CTIBQE connections:

```
hostname# show xlate debug
3 in use, 3 most used
Flags: D - DNS, d - dump, I - identity, i - inside, n - no random,
      r - portmap, s - static
TCP PAT from inside:10.0.0.99/1117 to outside:172.29.1.99/1025 flags ri idle 0:00:22
timeout 0:00:30
UDP PAT from inside:10.0.0.99/16908 to outside:172.29.1.99/1028 flags ri idle 0:00:00
timeout 0:04:10
UDP PAT from inside:10.0.0.99/16909 to outside:172.29.1.99/1029 flags ri idle 0:00:23
timeout 0:04:10
```

The `show conn state ctiqbe` command displays the status of CTIQBE connections. In the output, the media connections allocated by the CTIQBE inspection engine are denoted by a 'C' flag. The following is sample output from the `show conn state ctiqbe` command:

```
hostname# show conn state ctiqbe
1 in use, 10 most used
hostname# show conn state ctiqbe detail
1 in use, 10 most used
Flags: A - awaiting inside ACK to SYN, a - awaiting outside ACK to SYN,
      B - initial SYN from outside, C - CTIQBE media, D - DNS, d - dump,
      E - outside back connection, F - outside FIN, f - inside FIN,
      G - group, g - MGCP, H - H.323, h - H.225.0, I - inbound data,
      i - incomplete, J - GTP, j - GTP data, k - Skinny media,
      M - SMTP data, m - SIP media, O - outbound data, P - inside back connection,
      q - SQL*Net data, R - outside acknowledged FIN,
      R - UDP RPC, r - inside acknowledged FIN, S - awaiting inside SYN,
      s - awaiting outside SYN, T - SIP, t - SIP transient, U - up
```

## H.323 Inspection

This section describes the H.323 application inspection. This section includes the following topics:

- [H.323 Inspection Overview, page 40-4](#)
- [How H.323 Works, page 40-4](#)
- [H.239 Support in H.245 Messages, page 40-5](#)
- [Limitations and Restrictions, page 40-6](#)
- [Configuring an H.323 Inspection Policy Map for Additional Inspection Control, page 40-6](#)
- [Configuring H.323 and H.225 Timeout Values, page 40-9](#)
- [Verifying and Monitoring H.323 Inspection, page 40-9](#)

## H.323 Inspection Overview

H.323 inspection provides support for H.323 compliant applications such as Cisco CallManager and VocalTec Gatekeeper. H.323 is a suite of protocols defined by the International Telecommunication Union for multimedia conferences over LANs. The adaptive security appliance supports H.323 through Version 6, including H.323 v3 feature Multiple Calls on One Call Signaling Channel.

With H.323 inspection enabled, the adaptive security appliance supports multiple calls on the same call signaling channel, a feature introduced with H.323 Version 3. This feature reduces call setup time and reduces the use of ports on the adaptive security appliance.

The two major functions of H.323 inspection are as follows:

- NAT the necessary embedded IPv4 addresses in the H.225 and H.245 messages. Because H.323 messages are encoded in PER encoding format, the adaptive security appliance uses an ASN.1 decoder to decode the H.323 messages.
- Dynamically allocate the negotiated H.245 and RTP/RTCP connections.

## How H.323 Works

The H.323 collection of protocols collectively may use up to two TCP connection and four to eight UDP connections. FastConnect uses only one TCP connection, and RAS uses a single UDP connection for registration, admissions, and status.

An H.323 client can initially establish a TCP connection to an H.323 server using TCP port 1720 to request Q.931 call setup. As part of the call setup process, the H.323 terminal supplies a port number to the client to use for an H.245 TCP connection. In environments where H.323 gatekeeper is in use, the initial packet is transmitted using UDP.

H.323 inspection monitors the Q.931 TCP connection to determine the H.245 port number. If the H.323 terminals are not using FastConnect, the adaptive security appliance dynamically allocates the H.245 connection based on the inspection of the H.225 messages.

**Note**

---

The H.225 connection can also be dynamically allocated when using RAS.

---

Within each H.245 message, the H.323 endpoints exchange port numbers that are used for subsequent UDP data streams. H.323 inspection inspects the H.245 messages to identify these ports and dynamically creates connections for the media exchange. RTP uses the negotiated port number, while RTCP uses the next higher port number.

The H.323 control channel handles H.225 and H.245 and H.323 RAS. H.323 inspection uses the following ports.

- 1718—Gate Keeper Discovery UDP port
- 1719—RAS UDP port
- 1720—TCP Control Port

You must permit traffic for the well-known H.323 port 1719 for RAS signaling. Additionally, you must permit traffic for the well-known H.323 port 1720 for the H.225 call signaling; however, the H.245 signaling ports are negotiated between the endpoints in the H.225 signaling. When an H.323 gatekeeper is used, the adaptive security appliance opens an H.225 connection based on inspection of the ACF and RCF nmessages.

After inspecting the H.225 messages, the adaptive security appliance opens the H.245 channel and then inspects traffic sent over the H.245 channel as well. All H.245 messages passing through the adaptive security appliance undergo H.245 application inspection, which translates embedded IP addresses and opens the media channels negotiated in H.245 messages.

The H.323 ITU standard requires that a TPKT header, defining the length of the message, precede the H.225 and H.245, before being passed on to the reliable connection. Because the TPKT header does not necessarily need to be sent in the same TCP packet as H.225 and H.245 messages, the adaptive security appliance must remember the TPKT length to process and decode the messages properly. For each connection, the adaptive security appliance keeps a record that contains the TPKT length for the next expected message.

If the adaptive security appliance needs to perform NAT on IP addresses in messages, it changes the checksum, the UUIE length, and the TPKT, if it is included in the TCP packet with the H.225 message. If the TPKT is sent in a separate TCP packet, the adaptive security appliance proxy ACKs that TPKT and appends a new TPKT to the H.245 message with the new length.

**Note**

The adaptive security appliance does not support TCP options in the Proxy ACK for the TPKT.

Each UDP connection with a packet going through H.323 inspection is marked as an H.323 connection and times out with the H.323 timeout as configured with the **timeout** command.

**Note**

You can enable call setup between H.323 endpoints when the Gatekeeper is inside the network. The adaptive security appliance includes options to open pinholes for calls based on the RegistrationRequest/RegistrationConfirm (RRQ/RCF) messages. Because these RRQ/RCF messages are sent to and from the Gatekeeper, the calling endpoint's IP address is unknown and the adaptive security appliance opens a pinhole through source IP address/port 0/0. By default, this option is disabled. To enable call setup between H.323 endpoint, enter the **ras-rcf-pinholes enable** command during parameter configuration mode while creating an H.323 Inspection policy map. See [Configuring an H.323 Inspection Policy Map for Additional Inspection Control](#), page 40-6.

## H.239 Support in H.245 Messages

The adaptive security appliance sits between two H.323 endpoints. When the two H.323 endpoints set up a telepresence session so that the endpoints can send and receive a data presentation, such as spreadsheet data, the adaptive security appliance ensure successful H.239 negotiation between the endpoints.

H.239 is a standar that provides the ability for H.300 series endpoints to open an additional video channel in a single call. In a call, an endpoint (such as a video phone), sends a channel for video and a channel for data presentation. The H.239 negotiation occurs on the H.245 channel.

The adaptive security appliance opens pinholes for the additional media channel and the media control channel. The endpoints use open logical channel message (OLC) to signal a new channel creation. The message extension is part of H.245 version 13.

The decoding and encoding of of the telepresence session is enabled by default. H.239 encoding and decoding is preformed by ASN.1 coder.

## Limitations and Restrictions

The following are some of the known issues and limitations when using H.323 application inspection:

- Static PAT may not properly translate IP addresses embedded in optional fields within H.323 messages. If you experience this kind of problem, do not use static PAT with H.323.
- H.323 application inspection is not supported with NAT between same-security-level interfaces.
- When a NetMeeting client registers with an H.323 gatekeeper and tries to call an H.323 gateway that is also registered with the H.323 gatekeeper, the connection is established but no voice is heard in either direction. This problem is unrelated to the adaptive security appliance.
- If you configure a network static address where the network static address is the same as a third-party netmask and address, then any outbound H.323 connection fails.

## Configuring an H.323 Inspection Policy Map for Additional Inspection Control

To specify actions when a message violates a parameter, create an H.323 inspection policy map. You can then apply the inspection policy map when you enable H.323 inspection.

To create an H.323 inspection policy map, perform the following steps:

- 
- Step 1** (Optional) Add one or more regular expressions for use in traffic matching commands according to the “[Creating a Regular Expression](#)” section on page 11-12. See the types of text you can match in the **match** commands described in [Step 3](#).
- Step 2** (Optional) Create one or more regular expression class maps to group regular expressions according to the “[Creating a Regular Expression Class Map](#)” section on page 11-15.s
- Step 3** (Optional) Create an H.323 inspection class map by performing the following steps.

A class map groups multiple traffic matches. Traffic must match *all* of the **match** commands to match the class map. You can alternatively identify **match** commands directly in the policy map. The difference between creating a class map and defining the traffic match directly in the inspection policy map is that the class map lets you create more complex match criteria, and you can reuse class maps.

To specify traffic that should not match the class map, use the **match not** command. For example, if the **match not** command specifies the string “example.com,” then any traffic that includes “example.com” does not match the class map.

For the traffic that you identify in this class map, you can specify actions such as drop-connection, reset, and/or log the connection in the inspection policy map.

If you want to perform different actions for each **match** command, you should identify the traffic directly in the policy map.

- a.** Create the class map by entering the following command:

```
hostname(config)# class-map type inspect h323 [match-all | match-any] class_map_name
hostname(config-cmap)#
```

Where *the class\_map\_name* is the name of the class map. The **match-all** keyword is the default, and specifies that traffic must match all criteria to match the class map. The **match-any** keyword specifies that the traffic matches the class map if it matches at least one of the criteria. The CLI enters class-map configuration mode, where you can enter one or more **match** commands.

- b.** (Optional) To add a description to the class map, enter the following command:

```
hostname(config-cmap)# description string
```

Where *string* is the description of the class map (up to 200 characters).

- c. (Optional) To match a called party, enter the following command:

```
hostname(config-cmap)# match [not] called-party regex {class class_name | regex_name}
```

Where the **regex** *regex\_name* argument is the regular expression you created in [Step 1](#). The **class** *regex\_class\_name* is the regular expression class map you created in [Step 2](#).

- d. (Optional) To match a media type, enter the following command:

```
hostname(config-cmap)# match [not] media-type {audio | data | video}
```

- Step 4** Create an H.323 inspection policy map, enter the following command:

```
hostname(config)# policy-map type inspect h323 policy_map_name
hostname(config-pmap)#
```

Where the *policy\_map\_name* is the name of the policy map. The CLI enters policy-map configuration mode.

- Step 5** (Optional) To add a description to the policy map, enter the following command:

```
hostname(config-pmap)# description string
```

- Step 6** To apply actions to matching traffic, perform the following steps.

- a. Specify the traffic on which you want to perform actions using one of the following methods:

- Specify the H.323 class map that you created in [Step 3](#) by entering the following command:

```
hostname(config-pmap)# class class_map_name
hostname(config-pmap-c)#
```

- Specify traffic directly in the policy map using one of the **match** commands described in [Step 3](#). If you use a **match not** command, then any traffic that does not match the criterion in the **match not** command has the action applied.

- b. Specify the action you want to perform on the matching traffic by entering the following command:

```
hostname(config-pmap-c)# {[drop [send-protocol-error] |
drop-connection [send-protocol-error] | mask | reset] [log] | rate-limit message_rate}
```

Not all options are available for each **match** or **class** command. See the CLI help or the *Cisco ASA 5500 Series Command Reference* for the exact options available.

The **drop** keyword drops all packets that match.

The **send-protocol-error** keyword sends a protocol error message.

The **drop-connection** keyword drops the packet and closes the connection.

The **mask** keyword masks out the matching portion of the packet.

The **reset** keyword drops the packet, closes the connection, and sends a TCP reset to the server and/or client.

The **log** keyword, which you can use alone or with one of the other keywords, sends a system log message.

The **rate-limit** *message\_rate* argument limits the rate of messages.

You can specify multiple **class** or **match** commands in the policy map. For information about the order of **class** and **match** commands, see the “[Defining Actions in an Inspection Policy Map](#)” section on [page 31-2](#).

**Step 7** To configure parameters that affect the inspection engine, perform the following steps:

- a. To enter parameters configuration mode, enter the following command:

```
hostname(config-pmap) # parameters
hostname(config-pmap-p) #
```

- b. To enable call setup between H.323 Endpoints, enter the following command:

```
hostname(config) # ras-rcf-pinholes enable
```

You can enable call setup between H.323 endpoints when the Gatekeeper is inside the network. The adaptive security appliance includes options to open pinholes for calls based on the RegistrationRequest/RegistrationConfirm (RRQ/RCF) messages. Because these RRQ/RCF messages are sent to and from the Gatekeeper, the calling endpoint's IP address is unknown and the adaptive security appliance opens a pinhole through source IP address/port 0/0. By default, this option is disabled.

- c. To define the H.323 call duration limit, enter the following command:

```
hostname(config-pmap-p) # call-duration-limit time
```

Where *time* is the call duration limit in seconds. Range is from 0:0:0 to 1163:0:0. A value of 0 means never timeout.

- d. To enforce call party number used in call setup, enter the following command:

```
hostname(config-pmap-p) # call-party-number
```

- e. To enforce H.245 tunnel blocking, enter the following command:

```
hostname(config-pmap-p) # h245-tunnel-block action {drop-connection | log}
```

- f. To define an hsi group and enter hsi group configuration mode, enter the following command:

```
hostname(config-pmap-p) # hsi-group id
```

Where *id* is the hsi group ID. Range is from 0 to 2147483647.

To add an hsi to the hsi group, enter the following command in hsi group configuration mode:

```
hostname(config-h225-map-hsi-grp) # hsi ip_address
```

Where *ip\_address* is the host to add. A maximum of five hosts per hsi group are allowed.

To add an endpoint to the hsi group, enter the following command in hsi group configuration mode:

```
hostname(config-h225-map-hsi-grp) # endpoint ip_address if_name
```

Where *ip\_address* is the endpoint to add and *if\_name* is the interface through which the endpoint is connected to the security appliance. A maximum of ten endpoints per hsi group are allowed.

- g. To check RTP packets flowing on the pinholes for protocol conformance, enter the following command:

```
hostname(config-pmap-p) # rtp-conformance [enforce-payloadtype]
```

Where the **enforce-payloadtype** keyword enforces the payload type to be audio or video based on the signaling exchange.

- h. To enable state checking validation, enter the following command:

```
hostname(config-pmap-p) # state-checking {h225 | ras}
```

The following example shows how to configure phone number filtering:

```
hostname(config)# regex caller 1 "5551234567"
hostname(config)# regex caller 2 "5552345678"
hostname(config)# regex caller 3 "5553456789"

hostname(config)# class-map type inspect h323 match-all h323_traffic
hostname(config-pmap-c)# match called-party regex caller1
hostname(config-pmap-c)# match calling-party regex caller2

hostname(config)# policy-map type inspect h323 h323_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# class h323_traffic
hostname(config-pmap-c)# drop
```

## Configuring H.323 and H.225 Timeout Values

To configure the idle time after which an H.225 signalling connection is closed, use the **timeout h225** command. The default for H.225 timeout is one hour.

To configure the idle time after which an H.323 control connection is closed, use the **timeout h323** command. The default is five minutes.

## Verifying and Monitoring H.323 Inspection

This section describes how to display information about H.323 sessions. This section includes the following topics:

- [Monitoring H.225 Sessions, page 40-9](#)
- [Monitoring H.245 Sessions, page 40-10](#)
- [Monitoring H.323 RAS Sessions, page 40-10](#)

### Monitoring H.225 Sessions

The **show h225** command displays information for H.225 sessions established across the adaptive security appliance. Along with the **debug h323 h225 event**, **debug h323 h245 event**, and **show local-host** commands, this command is used for troubleshooting H.323 inspection engine issues.

Before entering the **show h225**, **show h245**, or **show h323-ras** commands, we recommend that you configure the **pager** command. If there are a lot of session records and the **pager** command is not configured, it may take a while for the **show** command output to reach its end. If there is an abnormally large number of connections, check that the sessions are timing out based on the default timeout values or the values set by you. If they are not, then there is a problem that needs to be investigated.

The following is sample output from the **show h225** command:

```
hostname# show h225
Total H.323 Calls: 1
1 Concurrent Call(s) for
  Local: 10.130.56.3/1040 Foreign: 172.30.254.203/1720
  1. CRV 9861
  Local: 10.130.56.3/1040 Foreign: 172.30.254.203/1720
0 Concurrent Call(s) for
  Local: 10.130.56.4/1050 Foreign: 172.30.254.205/1720
```

This output indicates that there is currently 1 active H.323 call going through the adaptive security appliance between the local endpoint 10.130.56.3 and foreign host 172.30.254.203, and for these particular endpoints, there is 1 concurrent call between them, with a CRV for that call of 9861.

For the local endpoint 10.130.56.4 and foreign host 172.30.254.205, there are 0 concurrent calls. This means that there is no active call between the endpoints even though the H.225 session still exists. This could happen if, at the time of the **show h225** command, the call has already ended but the H.225 session has not yet been deleted. Alternately, it could mean that the two endpoints still have a TCP connection opened between them because they set “maintainConnection” to TRUE, so the session is kept open until they set it to FALSE again, or until the session times out based on the H.225 timeout value in your configuration.

## Monitoring H.245 Sessions

The **show h245** command displays information for H.245 sessions established across the adaptive security appliance by endpoints using slow start. Slow start is when the two endpoints of a call open another TCP control channel for H.245. Fast start is where the H.245 messages are exchanged as part of the H.225 messages on the H.225 control channel.) Along with the **debug h323 h245 event**, **debug h323 h225 event**, and **show local-host** commands, this command is used for troubleshooting H.323 inspection engine issues.

The following is sample output from the **show h245** command:

```
hostname# show h245
Total: 1
      LOCAL          TPKT    FOREIGN          TPKT
1      10.130.56.3/1041      0      172.30.254.203/1245      0
      MEDIA: LCN 258 Foreign 172.30.254.203 RTP 49608 RTCP 49609
              Local  10.130.56.3 RTP 49608 RTCP 49609
      MEDIA: LCN 259 Foreign 172.30.254.203 RTP 49606 RTCP 49607
              Local  10.130.56.3 RTP 49606 RTCP 49607
```

There is currently one H.245 control session active across the adaptive security appliance. The local endpoint is 10.130.56.3, and we are expecting the next packet from this endpoint to have a TPKT header because the TPKT value is 0. The TKTP header is a 4-byte header preceding each H.225/H.245 message. It gives the length of the message, including the 4-byte header. The foreign host endpoint is 172.30.254.203, and we are expecting the next packet from this endpoint to have a TPKT header because the TPKT value is 0.

The media negotiated between these endpoints have an LCN of 258 with the foreign RTP IP address/port pair of 172.30.254.203/49608 and an RTCP IP address/port of 172.30.254.203/49609 with a local RTP IP address/port pair of 10.130.56.3/49608 and an RTCP port of 49609.

The second LCN of 259 has a foreign RTP IP address/port pair of 172.30.254.203/49606 and an RTCP IP address/port pair of 172.30.254.203/49607 with a local RTP IP address/port pair of 10.130.56.3/49606 and RTCP port of 49607.

## Monitoring H.323 RAS Sessions

The **show h323-ras** command displays information for H.323 RAS sessions established across the adaptive security appliance between a gatekeeper and its H.323 endpoint. Along with the **debug h323 ras event** and **show local-host** commands, this command is used for troubleshooting H.323 RAS inspection engine issues.

The **show h323-ras** command displays connection information for troubleshooting H.323 inspection engine issues. The following is sample output from the **show h323-ras** command:

```
hostname# show h323-ras
```

```
Total: 1
      GK                Caller
      172.30.254.214  10.130.56.14
```

This output shows that there is one active registration between the gatekeeper 172.30.254.214 and its client 10.130.56.14.

## MGCP Inspection

This section describes MGCP application inspection. This section includes the following topics:

- [MGCP Inspection Overview, page 40-11](#)
- [Configuring an MGCP Inspection Policy Map for Additional Inspection Control, page 40-13](#)
- [Configuring MGCP Timeout Values, page 40-14](#)
- [Verifying and Monitoring MGCP Inspection, page 40-14](#)

## MGCP Inspection Overview

MGCP is a master/slave protocol used to control media gateways from external call control elements called media gateway controllers or call agents. A media gateway is typically a network element that provides conversion between the audio signals carried on telephone circuits and data packets carried over the Internet or over other packet networks. Using NAT and PAT with MGCP lets you support a large number of devices on an internal network with a limited set of external (global) addresses. Examples of media gateways are:

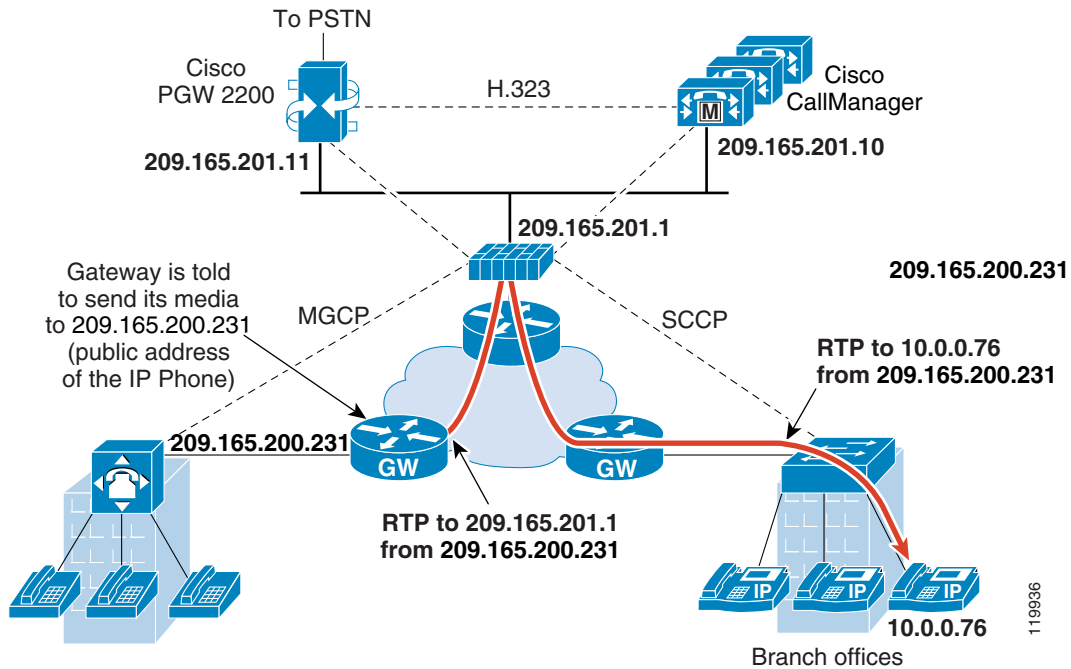

- Trunking gateways, that interface between the telephone network and a Voice over IP network. Such gateways typically manage a large number of digital circuits.
- Residential gateways, that provide a traditional analog (RJ11) interface to a Voice over IP network. Examples of residential gateways include cable modem/cable set-top boxes, xDSL devices, broad-band wireless devices.
- Business gateways, that provide a traditional digital PBX interface or an integrated soft PBX interface to a Voice over IP network.

### Note

To avoid policy failure when upgrading from ASA version 7.1, all layer 7 and layer 3 policies must have distinct names. For instance, a previously configured policy map with the same name as a previously configured MGCP map must be changed before the upgrade.

MGCP messages are transmitted over UDP. A response is sent back to the source address (IP address and UDP port number) of the command, but the response may not arrive from the same address as the command was sent to. This can happen when multiple call agents are being used in a failover configuration and the call agent that received the command has passed control to a backup call agent, which then sends the response. [Figure 40-1](#) illustrates how NAT can be used with MGCP.

**Figure 40-1** Using NAT with MGCP

MGCP endpoints are physical or virtual sources and destinations for data. Media gateways contain endpoints on which the call agent can create, modify and delete connections to establish and control media sessions with other multimedia endpoints. Also, the call agent can instruct the endpoints to detect certain events and generate signals. The endpoints automatically communicate changes in service state to the call agent.

MGCP transactions are composed of a command and a mandatory response. There are eight types of commands:

- CreateConnection
- ModifyConnection
- DeleteConnection
- NotificationRequest
- Notify
- AuditEndpoint
- AuditConnection
- RestartInProgress

The first four commands are sent by the call agent to the gateway. The Notify command is sent by the gateway to the call agent. The gateway may also send a DeleteConnection. The registration of the MGCP gateway with the call agent is achieved by the RestartInProgress command. The AuditEndpoint and the AuditConnection commands are sent by the call agent to the gateway.

All commands are composed of a Command header, optionally followed by a session description. All responses are composed of a Response header, optionally followed by a session description.

- The port on which the gateway receives commands from the call agent. Gateways usually listen to UDP port 2427.

- The port on which the call agent receives commands from the gateway. Call agents usually listen to UDP port 2727.

**Note**

MGCP inspection does not support the use of different IP addresses for MGCP signaling and RTP data. A common and recommended practice is to send RTP data from a resilient IP address, such as a loopback or virtual IP address; however, the adaptive security appliance requires the RTP data to come from the same address as MGCP signalling.

## Configuring an MGCP Inspection Policy Map for Additional Inspection Control

If the network has multiple call agents and gateways for which the adaptive security appliance has to open pinholes, create an MGCP map. You can then apply the MGCP map when you enable MGCP inspection.

To create an MGCP map, perform the following steps:

- Step 1** To create an MGCP inspection policy map, enter the following command:

```
hostname(config)# policy-map type inspect mgcp map_name
hostname(config-pmap)#
```

Where the *policy\_map\_name* is the name of the policy map. The CLI enters policy-map configuration mode.

- Step 2** (Optional) To add a description to the policy map, enter the following command:

```
hostname(config-pmap)# description string
```

- Step 3** To configure parameters that affect the inspection engine, perform the following steps:

- a. To enter parameters configuration mode, enter the following command:

```
hostname(config-pmap)# parameters
hostname(config-pmap-p)#
```

- b. To configure the call agents, enter the following command for each call agent:

```
hostname(config-pmap-p)# call-agent ip_address group_id
```

Use the **call-agent** command to specify a group of call agents that can manage one or more gateways. The call agent group information is used to open connections for the call agents in the group (other than the one a gateway sends a command to) so that any of the call agents can send the response. call agents with the same *group\_id* belong to the same group. A call agent may belong to more than one group. The *group\_id* option is a number from 0 to 4294967295. The *ip\_address* option specifies the IP address of the call agent.

**Note**

MGCP call agents send AUEP messages to determine if MGCP end points are present. This establishes a flow through the adaptive security appliance and allows MGCP end points to register with the call agent.

- c. To configure the gateways, enter the following command for each gateway:

```
hostname(config-pmap-p)# gateway ip_address group_id
```

Use the **gateway** command to specify which group of call agents are managing a particular gateway. The IP address of the gateway is specified with the *ip\_address* option. The *group\_id* option is a number from 0 to 4294967295 that must correspond with the *group\_id* of the call agents that are managing the gateway. A gateway may only belong to one group.

- d. If you want to change the maximum number of commands allowed in the MGCP command queue, enter the following command:

```
hostname(config-pmap-p)# command-queue command_limit
```

The following example shows how to define an MGCP map:

```
hostname(config)# policy-map type inspect mgcp sample_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# call-agent 10.10.11.5 101
hostname(config-pmap-p)# call-agent 10.10.11.6 101
hostname(config-pmap-p)# call-agent 10.10.11.7 102
hostname(config-pmap-p)# call-agent 10.10.11.8 102
hostname(config-pmap-p)# gateway 10.10.10.115 101
hostname(config-pmap-p)# gateway 10.10.10.116 102
hostname(config-pmap-p)# gateway 10.10.10.117 102
hostname(config-pmap-p)# command-queue 150
```

## Configuring MGCP Timeout Values

The **timeout mgcp** command lets you set the interval for inactivity after which an MGCP media connection is closed. The default is 5 minutes.

The **timeout mgcp-pat** command lets you set the timeout for PAT xlates. Because MGCP does not have a keepalive mechanism, if you use non-Cisco MGCP gateways (call agents), the PAT xlates are torn down after the default timeout interval, which is 30 seconds.

## Verifying and Monitoring MGCP Inspection

The **show mgcp commands** command lists the number of MGCP commands in the command queue. The **show mgcp sessions** command lists the number of existing MGCP sessions. The **detail** option includes additional information about each command (or session) in the output. The following is sample output from the **show mgcp commands** command:

```
hostname# show mgcp commands
1 in use, 1 most used, 200 maximum allowed
CRCX, gateway IP: host-pc-2, transaction ID: 2052, idle: 0:00:07
```

The following is sample output from the **show mgcp detail** command.

```
hostname# show mgcp commands detail
1 in use, 1 most used, 200 maximum allowed
CRCX, idle: 0:00:10
    Gateway IP      host-pc-2
    Transaction ID  2052
    Endpoint name   aaln/1
    Call ID         9876543210abcdef
    Connection ID
    Media IP        192.168.5.7
    Media port      6058
```

The following is sample output from the **show mgcp sessions** command.

```
hostname# show mgcp sessions
1 in use, 1 most used
Gateway IP host-pc-2, connection ID 6789af54c9, active 0:00:11
```

The following is sample output from the **show mgcp sessions detail** command.

```
hostname# show mgcp sessions detail
1 in use, 1 most used
Session active 0:00:14
    Gateway IP      host-pc-2
    Call ID         9876543210abcdef
    Connection ID   6789af54c9
    Endpoint name   aaln/1
    Media lcl port  6166
    Media rmt IP    192.168.5.7
    Media rmt port  6058
```

## RTSP Inspection

This section describes RTSP application inspection. This section includes the following topics:

- [RTSP Inspection Overview, page 40-15](#)
- [Using RealPlayer, page 40-16](#)
- [Restrictions and Limitations, page 40-16](#)
- [Configuring an RTSP Inspection Policy Map for Additional Inspection Control, page 40-16](#)

## RTSP Inspection Overview

The RTSP inspection engine lets the adaptive security appliance pass RTSP packets. RTSP is used by RealAudio, RealNetworks, Apple QuickTime 4, RealPlayer, and Cisco IP/TV connections.

### Note

For Cisco IP/TV, use RTSP TCP port 554 and TCP 8554.
